## CHAPTER 4 -- KINEMATICS

## 4.1)

a.) The total distance traversed (versus the net displacement) divided by the elapsed time. That scalar is:

$$
\begin{aligned}
\mathrm{s} & =\operatorname{dist} / \text { time } \\
& =(440 \mathrm{~m}) /(49 \mathrm{sec}) \\
& =8.98 \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

b.) The magnitude of the average velocity is the net displacement divided by the elapsed time. That is:

$$
\begin{aligned}
\mathbf{v} & =(\text { net disp }) / \text { time } \\
& =(0 \mathrm{~m}) /(49 \mathrm{sec}) \\
& =0 \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

Making sense of this: The woman finished where she started, so her net displacement is zero. The average velocity tells us the constant velocity she would have to travel to effect that displacement in 49 seconds. That velocity is zero!
c.) You know nothing about her instantaneous velocity at any point in the motion--not even at the beginning (for all you know, she may have had a running start).
4.2) The only options we have are:
a.) The curve could be an acceleration versus time graph. For a given time interval, the area under such a curve yields the velocity change over the interval. As we have not been told about time intervals or velocity changes, we don't have enough information to say yea or nay.
b.) The curve could be a velocity versus time curve. If that be so, the velocity magnitude at $t=1$ second should be $v=-1 \mathrm{~m} / \mathrm{s}$. Unfortunately, the graph reads +1 at $t=1$ second. The graph is not a velocity versus time graph.
c.) The slope of the tangent to a distance versus time graph at any given point equals the instantaneous velocity at that point in time. Taking the curve's slope at $t=1$ second we get -1 . The curve must, therefore, be a position versus time graph.

## 4.3)

a.) During a given time interval, the net displacement of a body is equal to the area under the velocity versus time curve. The area under the curve between $t=.5$ seconds and $t=3$ seconds has two parts: one above the axis and one below the axis.

Noting that one square on the graph is equal to $1 / 8$ meter, the area above the axis is eyeballed at approximately (+2.3 squares)(1/8 meter/square), or +.29 meters. The area below the axis is eyeballed at approximately ( -22 squ )(1/8 meter/squ), or -2.75 meters.

The net distance traveled is approximately $(.29 \mathrm{~m})+(-2.75 \mathrm{~m})=-2.46$ meters. That is, the ant travels 2.46 meters to the left of its starting point.

Note 1: This number is not the ant's final position-coordinate. It is only the net distance the ant traveled from its original position during the time interval.

Note 2: Written out fully, $\Delta \boldsymbol{x}=-2.46 \boldsymbol{i}$ meters.
b.) Average velocity is defined as the net displacement per unit time over a time interval. In Part $a$, we determined the ant's net displacement between the .5 second and 3 second mark as -2.46 meters. As the time interval is 2.5 seconds:

$$
\begin{aligned}
\mathrm{v}_{\mathrm{avg}} & =(\text { net disp }) /(\text { time interval }) \\
& =(-2.46 \mathbf{i} \text { meters }) /(2.5 \text { seconds }) \\
& =-.98 \mathbf{i} \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

c.) Taking the information directly off the graph, the ant's velocity:
i.) At $t=.5$ seconds is approximately $1.3 \mathbf{i} \mathrm{~m} / \mathrm{s}$.
ii.) At $t=3$ seconds is approximately $-2.1 \mathbf{i} \mathrm{~m} / \mathrm{s}$.
d.) At a given point in time, the acceleration (i.e., the change of velocity with time) is the slope of the tangent to the velocity curve. Eyeballing it (watch the graph scaling), the slope of the tangent at:
i.) $t=.5$ seconds is approximately (-2)/(.5), or $\boldsymbol{a}=-4 \boldsymbol{i} \mathrm{~m} / \mathrm{s}^{2}$.
ii.) $t=3$ seconds is approximately (1)/(2.25), or $\boldsymbol{a}=+.44 \boldsymbol{i} \mathrm{~m} / \mathrm{s}^{2}$.
e.) When the velocity is positive, the ant is moving in the $+x$ direction (the direction of motion is the direction of the instantaneous velocity). This occurs between $t=.3$ seconds and $t=1$ second.
f.) When the velocity is zero, the ant is standing still. This occurs at $t$ $=1$ second .
g.) The acceleration is zero when the slope of the tangent to the curve is zero (that is, when the velocity is not changing). This occurs at times $t=$ 2.9 seconds and $t=3.6$ seconds.
h.) When the slope of the velocity graph changes, we have what are called inflection points. To determine one, we need to observe two things:
i.) When the acceleration is not changing, the acceleration is constant.
ii.) A constant acceleration generates a velocity function that changes linearly (i.e., the velocity changes at a constant rate).

The interval over which the velocity seems to be changing linearly is between $t=.3$ seconds and $t=.5$ seconds, at 3.25 seconds, and maybe between $t$ $=4$ seconds and $t=4.3$ seconds (though this latter suggestion is debatable).
4.4) The velocity function is $\boldsymbol{v}(t)=\left(3 e^{-1.5 k t} \boldsymbol{i}-4 k_{1} t \boldsymbol{j}\right) \mathrm{m} / \mathrm{s}$. Noting that the constant $k=1 \mathrm{sec}^{-1}$ (the only way the exponent in $e^{-k t}$ can be unitless is if $k^{\prime} s$ units are $1 /$ seconds) and $k_{1}=1 \mathrm{~m} / \mathrm{s}^{2}$ :
a.) Omitting the $k$ terms (their magnitudes are "1"--they are present only for the sake of units), we can plug $t=2$ seconds into the velocity function yielding:

$$
\begin{aligned}
\mathbf{v}(\mathrm{t}) & =\left(3 \mathrm{e}^{-1.5 \mathrm{t}} \mathbf{i}-4 \mathrm{t} \mathbf{j}\right) \mathrm{m} / \mathrm{s} \\
& =\left[3 \mathrm{e}^{-(1.5)(2)} \mathbf{i}-4(2) \mathbf{j}\right] \mathrm{m} / \mathrm{s} \\
& =[.15 \mathbf{i}-8 \mathbf{j}] \mathrm{m} / \mathrm{s}
\end{aligned}
$$

b.) Acceleration is the time derivative of the velocity function, or:

$$
\begin{aligned}
\mathbf{a}(\mathrm{t}) & =\mathrm{d} \mathbf{v}(\mathrm{t}) / \mathrm{dt} \\
& =\mathrm{d}\left(3 \mathrm{e}^{-1.5 \mathrm{t}} \mathbf{i}-4 \mathrm{t} \mathbf{j}\right) / \mathrm{dt} \\
& =\left[-4.5 \mathrm{e}^{-1.5 \mathrm{t}} \mathbf{i}-4 \mathbf{j}\right] \mathrm{m} / \mathrm{s}^{2} .
\end{aligned}
$$

c.) Plugging $t=2$ seconds into the acceleration function yields:

$$
\begin{aligned}
\mathbf{a} & =\left[-4.5 \mathrm{e}^{-1.5(2)} \mathbf{i}-4 \mathbf{j}\right] \mathrm{m} / \mathrm{s}^{2} \\
& =[-.22 \mathbf{i}-4 \mathbf{j}] \mathrm{m} / \mathrm{s}^{2}
\end{aligned}
$$

d.) Using the kinematic equations requires a constant acceleration. In this case, there are two accelerations to consider--one in the $x$ direction and one in the $y$ direction (they are independent of one another).
i.) The $x$ component of acceleration is time dependent. That is, it is not a constant. As such, the kinematic equations will not be valid for the body's $x$-type motion.
ii.) The $y$ component of the acceleration is constant ( $a_{y}=4 \mathrm{~m} / \mathrm{s}^{2}$ ). Kinematics will work on problems associated with the body's $y$-type motion.
e.) The body's position function $\boldsymbol{r}$ is determined by integrating the velocity function $\boldsymbol{v}(t)$ over an indefinite time interval (i.e., by solving $\int(\boldsymbol{v}) d t$ without evaluating between times $t_{1}$ and $t_{2}$ ). Executing that operation, we get:

$$
\begin{aligned}
\mathbf{r}(\mathrm{t}) & =\int \mathbf{v}(\mathrm{t}) \mathrm{dt} \\
& =\int\left[\left(3 \mathrm{e}^{-1.5 \mathrm{t}} \mathbf{i}-4 \mathrm{t} \mathbf{j}\right] \mathrm{dt}\right. \\
& =\int\left[\left(3 \mathrm{e}^{-1.5 \mathrm{t}} \mathbf{i}\right] \mathrm{dt}+\int[(-4 \mathrm{t} \mathbf{j}] \mathrm{dt}\right. \\
& =\left(\left[-2 \mathrm{e}^{-1.5 \mathrm{t}} \mathbf{i}\right]+\left[-2 \mathrm{t}^{2} \mathbf{j}\right]\right) \text { meters. }
\end{aligned}
$$

Notice there is no evaluation done here. All the problem asked for was the function that defines the position $\boldsymbol{r}(t)$ for the body. Note also that the derivative of $\boldsymbol{r}(t)$ yields $\boldsymbol{v}(t)$.
f.) To find the displacement, we must evaluate the position function at $t=2$ seconds and $t=3.5$ seconds, then subtract the two to get the net change of position (that is what the net displacement is). Doing so yields:

$$
\begin{aligned}
\Delta \mathbf{r} & =\left[\left[-2 \mathrm{e}^{-1.5 \mathbf{i}} \mathbf{i}\right]+\left[-2 \mathrm{t}^{2} \mathbf{j}\right]\right]_{\mathrm{t}=2 \mathrm{sec}}^{3.5} \\
& =\left(\left[-2 \mathrm{e}^{-1.5(3.5)} \mathbf{i}\right]+\left[-2(3.5)^{2} \mathbf{j}\right]\right)-\left(\left[-2 \mathrm{e}^{-1.5(2)} \mathbf{i}\right]+\left[-2(2)^{2} \mathbf{j}\right]\right) \\
& =(-.01 \mathbf{i}-24.5 \mathbf{j})-(-.10 \mathbf{i}-8 \mathbf{j}) \\
& =[.09 \mathbf{i}-16.5 \mathbf{j}] \mathrm{m} .
\end{aligned}
$$

g.) The change of the body's position between $t=2$ seconds, and $t=3.5$ seconds is $\Delta \boldsymbol{r}=.09 \boldsymbol{i}-16.5 \mathbf{j}$. This change of position can also be written as $\Delta \boldsymbol{r}=\left(x_{2}-x_{1}\right) \boldsymbol{i}+\left(y_{2}-y_{1}\right) \boldsymbol{j}$. As the $x$-type motion and the $y$-type motion are independent of one another, we can separate the two and write:
for i motion:

$$
\begin{aligned}
(.09 \mathrm{~m}) & =\left(\mathrm{x}_{2}-\mathrm{x}_{1}\right) \\
& =\mathrm{x}_{2}-(-.1 \mathrm{~m}) \\
\Rightarrow \quad \mathrm{x}_{2} & =-.01 \text { meters. }
\end{aligned}
$$

for $\mathbf{j}$ motion:

$$
\begin{aligned}
(-16.5 \mathrm{~m}) & =\left(\mathrm{y}_{2}-\mathrm{y}_{1}\right) \\
& =\mathrm{y}_{2}-(-8 \mathrm{~m}) \\
\Rightarrow \quad \mathrm{y}_{2} & =-24.5 \text { meters. }
\end{aligned}
$$

Coordinates at $t=3.5$ seconds will be $x_{2}=-.01$ meters, $y_{2}=-24.5$ meters.
h.) The jerk is the time rate of change of the acceleration. That is:

$$
\begin{aligned}
\text { jerk } & =\mathrm{d} \mathbf{a} / \mathrm{dt} \\
& =\mathrm{d}\left[-4.5 \mathrm{e}^{-1.5 \mathrm{t}} \mathbf{i}-4 \mathbf{j}\right] / \mathrm{dt} \\
& =\left[6.75 \mathrm{e}^{-1.5 \mathrm{t}} \mathbf{i}\right] \mathrm{m} / \mathrm{s}^{3} .
\end{aligned}
$$

i.) Exponents must be unitless, so $k$ must have the units of seconds ${ }^{-1}$.
4.5) We know the bats' initial vertical velocity $v_{1}=0$, their initial height $h_{1}$ $=100$ meters, their pull-out height $h_{2}=3$ meters, and their acceleration $a$ is minus the magnitude of the acceleration of gravity, or $a=-g=-9.8 \mathrm{~m} / \mathrm{s}^{2}$ :
a.) We want $v_{2}$. Scanning the kinematic equations (shown below),

$$
\begin{aligned}
& \left(\mathrm{x}_{2}-\mathrm{x}_{1}\right)=\mathrm{v}_{1} \Delta \mathrm{t}+(1 / 2) \mathrm{a}(\Delta \mathrm{t})^{2} \\
& \left(\mathrm{x}_{2}-\mathrm{x}_{1}\right)=\mathrm{v}_{\mathrm{avg}} \Delta \mathrm{t} \quad \text { or } \quad \mathrm{v}_{\mathrm{avg}}=\left(\mathrm{x}_{2}-\mathrm{x}_{1}\right) / \Delta \mathrm{t} \\
& \mathrm{v}_{\mathrm{avg}}=\left(\mathrm{v}_{2}+\mathrm{v}_{1}\right) / 2 \\
& \mathrm{a}=\left(\mathrm{v}_{2}-\mathrm{v}_{1}\right) / \Delta \mathrm{t} \text { or } \mathrm{v}_{2}=\mathrm{v}_{1}+\mathrm{a} \Delta \mathrm{t}
\end{aligned}
$$

$$
\left(\mathrm{v}_{2}\right)^{2}=\left(\mathrm{v}_{1}\right)^{2}+2 \mathrm{a}\left(\mathrm{x}_{2}-\mathrm{x}_{1}\right),
$$

we decide to use:

$$
\begin{aligned}
& \left(\mathrm{v}_{2}\right)^{2}=\left(\mathrm{v}_{1}\right)^{2}+2 \mathrm{a}\left(\mathrm{x}_{2}-\mathrm{x}_{1}\right) \\
\Rightarrow \quad \mathrm{v}_{2}= & {\left[(0)^{2}+2\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)[(3 \mathrm{~m})-(100 \mathrm{~m})]\right]^{1 / 2} } \\
= & 43.6 \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

Note: This equation yields the magnitude of the velocity only (the quantity $v_{2}$ is squared in the equation). If we use this value in subsequent problems, we must make it negative (the body is moving downward in the $\boldsymbol{- j}$ direction).

$$
\Rightarrow \quad \mathbf{v}_{2}=-43.6 \mathbf{j} \mathrm{~m} / \mathrm{s}
$$

b.) We know that at 3 meters above the ground, $y_{2}=3$ meters and $v_{2}=-43.6 \mathrm{~m} / \mathrm{s}$ (we got the latter from Part $a$ ). We want the pull-out acceleration $a_{p}$ executed between $y_{2}=3$ meters and $y_{3}=1$ meter. Scanning the kinematic equations, we find that the same equation used in Part a will do the job:

$$
\begin{aligned}
& \left(\mathrm{v}_{3}\right)^{2}=\left(\mathrm{v}_{2}\right)^{2}+2 \mathrm{a}_{\mathrm{p}}\left(\mathrm{x}_{3}-\mathrm{x}_{2}\right) \\
& \quad \Rightarrow \quad(0)^{2}=(-43.6 \mathrm{~m} / \mathrm{s})^{2}+2 \mathrm{a}_{\mathrm{p}}[(1 \mathrm{~m})-(3 \mathrm{~m})] \\
& \quad \Rightarrow \quad \mathrm{a}_{\mathrm{p}}=475 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
$$

Note 1: We used the same equation in Parts $a$ and $b$ even though the two situations are related to entirely different sections of motion. The moral of the story: these equations work between $A N Y$ two points for which you have information.

Note 2: That the acceleration is positive should not be surprising. The net force and the acceleration are proportional; it will take a positive force (i.e., a force upward in the $+\boldsymbol{j}$ direction) to stop the bats' freefall.
c.) We know the velocity at the beginning of the pull-out ( $v_{2}=-43.6$ $\mathrm{m} / \mathrm{s}$ ), the velocity at the end of the pull-out $\left(v_{3}=0\right)$, and the acceleration through the pull-out ( $a_{p}=475 \mathrm{~m} / \mathrm{s}^{2}$ ). To determine the time:

$$
\mathrm{a}=\left(\mathrm{v}_{3}-\mathrm{v}_{2}\right) / \Delta \mathrm{t}
$$

$$
\begin{aligned}
\Rightarrow \quad \Delta \mathrm{t} & =\left(\mathrm{v}_{3}-\mathrm{v}_{2}\right) / \mathrm{a} \\
& =[(0)-(-43.6 \mathrm{~m} / \mathrm{s})] /\left(475 \mathrm{~m} / \mathrm{s}^{2}\right) \\
& =.092 \text { seconds. }
\end{aligned}
$$

4.6) $x(t)=b t^{4}-c t$ (plugging in $b=6$ and $c=2$, we get $x(t)=6 t^{4}-2 t$ ).
a.) The body will change its direction when reaches either its maximum or minimum $x$ position. At that point it will reverse its direction. The velocity at the turn-around point is ZERO. Ignoring unit vectors (it is one dimensional motion), the velocity function is:

$$
\begin{aligned}
\mathrm{v} & =\mathrm{dx} / \mathrm{dt} \\
& =\mathrm{d}\left[6 \mathrm{t}^{4}-2 \mathrm{t}\right] / \mathrm{dt} \\
& =24 \mathrm{t}^{3}-2 .
\end{aligned}
$$

Putting the body's velocity at the turn-around point equal to zero, we get:

$$
\begin{aligned}
24 \mathrm{t}^{3}-2= & 0 \\
\Rightarrow \quad \mathrm{t} & =(2 / 24)^{1 / 3} \\
& =.437 \text { seconds. }
\end{aligned}
$$

b.) If we can determine the time at which $a=+12 \mathrm{~m} / \mathrm{s}^{2}$, we can put that time back into our velocity function to determine the velocity of the body at that point in the motion. Knowing the velocity (sign and all) will tell us the direction of motion. Executing that plan:

$$
\begin{aligned}
\mathrm{a}(\mathrm{t}) & =\mathrm{dv}(\mathrm{t}) / \mathrm{dt} \\
& =\mathrm{d}\left[24 \mathrm{t}^{3}-2 \mathrm{t}\right] / \mathrm{dt} \\
& =72 \mathrm{t}^{2} .
\end{aligned}
$$

Putting this equal to $12 \mathrm{~m} / \mathrm{s}^{2}$ yields our time:

$$
\begin{aligned}
& 72 \mathrm{t}^{2}=12 \\
& \quad \Rightarrow \quad \mathrm{t}=.408 \text { seconds. }
\end{aligned}
$$

The velocity at $t=.408$ seconds is:

$$
\begin{aligned}
\mathrm{v} & =24 \mathrm{t}^{3}-2 \\
& =24(.408)^{3}-2 \\
& =-.37 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

As the velocity vector is negative, the body must be moving in the negative direction when the acceleration is $+12 \mathrm{~m} / \mathrm{s}^{2}$.
4.7) The stunt woman's velocity at $\operatorname{Point} A$ is $v_{A}=-25 \mathrm{~m} / \mathrm{s}$. The acceleration is still $a=-g$.
a.) After 2 seconds, she has moved a distance:

$$
\begin{aligned}
\left(\mathrm{x}_{\mathrm{B}}-\mathrm{x}_{\mathrm{A}}\right) & =\mathrm{v}_{\mathrm{A}} \Delta \mathrm{t}+(1 / 2) \mathrm{a}(\Delta \mathrm{t})^{2} \\
& =(-25 \mathrm{~m} / \mathrm{s})(2 \mathrm{sec})+.5\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(2 \mathrm{sec})^{2} \\
& =-69.6 \text { meters. }
\end{aligned}
$$

b.) Her velocity at Point $B$ :

$$
\begin{aligned}
{ }^{v_{B}} & =v_{A}+\mathrm{a} \Delta \mathrm{t} \\
& =(-25 \mathrm{~m} / \mathrm{s})+\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(2 \mathrm{sec}) \\
& =-44.6 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

4.8) Because there are two cars in the system, we have two sets of kinematic equations available to us (one for the motion of each car). There are two common quantities that will link the two sets of equations during the time interval between the first pass and the second pass. They are: 1.) both cars will travel for the same amount of time during the interval; and 2.) their last-pass coordinate will be the same (we'll call this the "final" coordinate for simplicity).

If we define the origin (i.e., $x_{1}=0$ ) at the point where the two cars first pass and define the last pass position as $x_{2}$ :
a.) For the first car whose initial velocity is $18 \mathrm{~m} / \mathrm{s}$ and whose acceleration is zero:

$$
\begin{array}{rlrl} 
& & \left(\mathrm{x}_{2}-\mathrm{x}_{1}\right) & =\mathrm{v}_{\mathrm{fst}, 1} \Delta \mathrm{t}+(1 / 2) \mathrm{a}_{\mathrm{fst}}(\Delta \mathrm{t})^{2} \\
\Rightarrow \quad\left(\mathrm{x}_{2}-0\right) & =(18 \mathrm{~m} / \mathrm{s}) \mathrm{t}+.5(0) \mathrm{t}^{2} \\
\Rightarrow \quad & \mathrm{x}_{2} & =18 \mathrm{t} \quad \text { (Equation 1). }
\end{array}
$$

--For the second car whose initial velocity is $4 \mathrm{~m} / \mathrm{s}$ and whose acceleration is $6 \mathrm{~m} / \mathrm{s}^{2}$ :

$$
\begin{aligned}
\left(\mathrm{x}_{2}-\mathrm{x}_{1}\right) & =\mathrm{v}_{\mathrm{sec}, 1} \Delta \mathrm{t}+(1 / 2) \mathrm{a}_{\mathrm{sec}}(\Delta \mathrm{t})^{2} \\
\Rightarrow \quad\left(\mathrm{x}_{2}-0\right) & =(4 \mathrm{~m} / \mathrm{s}) \mathrm{t}+.5\left(6 \mathrm{~m} / \mathrm{s}^{2}\right) \mathrm{t}^{2}
\end{aligned}
$$

$$
\Rightarrow \quad \mathrm{x}_{2}=4 \mathrm{t}+3 \mathrm{t}^{2}
$$

(Equation 2).
Equating the two independent expressions for $x_{2}$ (i.e., Equations 1 and 2) yields:

$$
18 \mathrm{t}=4 \mathrm{t}+3 \mathrm{t}^{2}
$$

Dividing by $t$ yields:

$$
\begin{array}{cc} 
& 18=4+3 \mathrm{t} \\
\Rightarrow \quad \mathrm{t}=4.67 \text { seconds. }
\end{array}
$$

b.) Using Equation 1 yields:

$$
\begin{aligned}
\mathrm{x}_{2} & =18 \mathrm{t} \\
& =18(4.67 \text { seconds }) \\
& =84.1 \text { meters. }
\end{aligned}
$$

Using Equation 2 yields:

$$
\begin{aligned}
\mathrm{x}_{2} & =4 \mathrm{t}+3 \mathrm{t}^{2} \\
& =4(4.67 \mathrm{sec})+3(4.67 \mathrm{sec})^{2} \\
& =84.1 \mathrm{~meters} .
\end{aligned}
$$

## EITHER EQUATION WILL DO!

c.) The second car's velocity as it passes the first car:

$$
\begin{aligned}
\mathrm{v}_{\mathrm{sec}, 2} & =\mathrm{v}_{\mathrm{sec}, 1}+\mathrm{a}_{\mathrm{sec}} \Delta \mathrm{t} \\
& =(4 \mathrm{~m} / \mathrm{s})+\left(6 \mathrm{~m} / \mathrm{s}^{2}\right)(4.67 \mathrm{sec}) \\
& =32.02 \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

An alternative approach would be:

$$
\begin{aligned}
\left(\mathrm{v}_{\mathrm{sec}, 2}\right)^{2} & =\left(\mathrm{v}_{\mathrm{sec}, 1}\right)^{2}+2 \mathrm{a}_{\mathrm{fst}}\left(\mathrm{x}_{\mathrm{p}}-\mathrm{x}_{\mathrm{o}}\right) \\
& =(4 \mathrm{~m} /)^{2}+2\left(6 \mathrm{~m} / \mathrm{s}^{2}\right)[(84.1 \mathrm{~m})-0] \\
& =32.02 \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

EITHER APPROACH WORKS!
d.) The second car's average velocity:

$$
\begin{aligned}
\mathrm{v}_{\mathrm{avg}} & =\left(\mathrm{v}_{\mathrm{sec}, 2}+\mathrm{v}_{\mathrm{sec}, 1}\right) / 2 \\
& =(32.02 \mathrm{~m} / \mathrm{s}+4 \mathrm{~m} / \mathrm{s}) / 2 \\
& =18.01 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

e.) Time for the second car to travel to a velocity of $100 \mathrm{~m} / \mathrm{s}$ :

$$
\begin{aligned}
\mathrm{a}_{\mathrm{sec}} & =\left(\mathrm{v}_{100}-\mathrm{v}_{\mathrm{sec}, 1}\right) / \Delta \mathrm{t} \\
\Rightarrow \quad \mathrm{Dt} & =(100 \mathrm{~m} / \mathrm{s}-4 \mathrm{~m} / \mathrm{s}) /\left(6 \mathrm{~m} / \mathrm{s}^{2}\right) \\
& =16 \text { seconds. }
\end{aligned}
$$

a.) All the known information has been inserted into the sketch to the right. The coordinate axis has been placed so that $y_{1}=0$ at the bottom of the window. We will proceed by writing out kinematic relationships that will allow us to solve for information we need. To determine the velocity of the rock when it is at the top of the window, we will define the "final" position to be at $y_{1}$ with an
 "initial" position at $y_{2}$. With that, we can write:

$$
\left.\left.\begin{array}{l}
\quad\left(\mathrm{y}_{1}-\mathrm{y}_{2}\right)=\mathrm{v}_{2} \Delta \mathrm{t}+(1 / 2) \mathrm{a}(\Delta \mathrm{t})^{2} \\
(0)-(1.75 \mathrm{~m})
\end{array}\right)=\mathrm{v}_{2}(.14 \mathrm{~s})+(1 / 2)\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.14 \mathrm{~s})^{2}\right) \text { ( } \begin{aligned}
\Rightarrow \quad \mathrm{v}_{2} & =\left[(-1.75 \mathrm{~m})-.5\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.14 \mathrm{~s})^{2}\right] /(.14 \mathrm{~s}) \\
& =-11.8 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

Note: The negative sign makes sense considering the fact that the rock is moving downward.
b.) We want the distance between the top of the building and the bottom of the window (this will numerically equal $y_{3}$ ). An equation with known values and $y_{3}$ is (note that the "final" position here is $y_{2}$ ):

$$
\begin{aligned}
\left(\mathrm{v}_{2}\right)^{2} & =\left(\mathrm{v}_{3}\right)^{2}+2 \mathrm{a} \quad\left(\mathrm{y}_{2}-\mathrm{y}_{3}\right) \\
(-11.8 \mathrm{~m} / \mathrm{s})^{2} & \left.=(-7 \mathrm{~m} / \mathrm{s})^{2}+2\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\left[(1.75 \mathrm{~m})-\mathrm{y}_{3}\right)\right] \\
\Rightarrow \quad y_{3} & =6.35 \text { meters. }
\end{aligned}
$$

c.) A change in the initial velocity of the rock does nothing to the acceleration of the rock. Once it becomes free, the rock picks up velocity due to gravity at a rate of $9.8 \mathrm{~m} / \mathrm{s}$ every second, no matter what. Tricky, eh?
4.10) The car's initial velocity is $v_{1}=40 \mathrm{~m} / \mathrm{s}$; its pedal-to-the-metal acceleration is $a_{g o}=+3 \mathrm{~m} / \mathrm{s}^{2}$ and its stopping acceleration is $a_{\text {stop }}=-3 \mathrm{~m} / \mathrm{s}^{2}$. The light stays yellow for 1.2 seconds before turning. We need to consider two situations: a.) what is the maximum distance the car can be from the restraining line if it is to successfully accelerate all the way through the intersection in 1.2 seconds; and b.) what is the minimum distance the car can be from the restraining line if it is to brake successfully?
a.) Pedal-to-the-metal: Taking $\Delta x_{g o}$ to be the distance from the restraining line to the point at which the car begins its acceleration, the car must go $\Delta x_{g o}+18$ meters to make it through the intersection without incident (remember, the intersection extends 18 meters beyond the restraining line). With 1.2 seconds to accomplish the feat, we can write:

$$
\begin{aligned}
\left(\Delta \mathrm{x}_{\mathrm{go}}+18\right) & =\mathrm{v}_{1} \Delta \mathrm{t}+(1 / 2) \mathrm{a}_{\mathrm{go}}(\Delta \mathrm{t})^{2} \\
\Rightarrow \quad \Delta \mathrm{x}_{\mathrm{go}} & =(-18 \mathrm{~m})+(40 \mathrm{~m} / \mathrm{s})(1.2 \mathrm{sec})+.5\left(+3 \mathrm{~m} / \mathrm{s}^{2}\right)(1.2 \mathrm{sec})^{2} \\
& =32.16 \text { meters }
\end{aligned}
$$

If the car is closer than 32.16 meters, it can accelerate and still make it across the intersection. If the car is farther than 32.16 meters, it will not be able to accelerate completely through the intersection.
b.) Braking: The 1.2 seconds is useless in this section. It doesn't matter whether the car is sliding while the light is red or not. All that matters is that the car stop just behind the restraining line. Putting the origin at the restraining line (i.e., $x_{r . l .}=0$ ), and defining $x_{b r a k e}$ to be the
position at which the brakes must be hit to effect the stop right at the restraining line, we can write:

$$
\left.\begin{array}{rl}
\mathrm{v}_{\mathrm{r} . \mathrm{l}}^{2} & =\mathrm{v}_{\text {brk }}^{2}+2 \mathrm{a}\left(\mathrm{x}_{\mathrm{r} . \mathrm{l} .}-\mathrm{x}_{\mathrm{brk}}\right) \\
\Rightarrow \quad \mathrm{x}_{\mathrm{brk}} & =-\left(\mathrm{v}_{\mathrm{r} . \mathrm{l} .}^{2}-\quad \mathrm{v}_{\mathrm{brk}}^{2}\right) /(2 \quad \mathrm{a}
\end{array}\right)
$$

Note: The negative sign simply means that a car moving to the right in the positive direction must begin to stop to the left of the origin (the restraining line).
c.) Bottom Line: The car eats it no matter what if it is between 267 meters and 32 meters of the restraining line.

### 4.11)

a.) We need a fixed coordinate axis from which to make our measurements. We could take ground level as our $y=0$ level, but instead we will take the position in space of the elevator's floor just as the bolt releases (this will be useful because it is the elevator's floor that will come in contact with the bolt at the collide position).

The bolt's initial velocity is the same as that of the elevator at the moment it becomes free. That velocity is upward, so the bolt will
 move above its suddenly-free position to some maximum position $y_{\max }$ before beginning to descend. WHENEVER YOU ARE LOOKING FOR $y_{\max }$, ALWAYS USE:

$$
\mathrm{v}_{\mathrm{top}}^{2}=\mathrm{v}_{1}^{2}+2 \mathrm{a}\left(\mathrm{y}_{\text {top }}-\mathrm{y}_{1}\right) .
$$

As we know the bolt's velocity at the top of its motion is $v_{t o p}=0$, we can write:

$$
\begin{aligned}
& \mathrm{v}_{\text {top }}^{2}=\mathrm{v}_{1, \mathrm{~b}}^{2}+2 \mathrm{a}_{\mathrm{b}}\left(\mathrm{y}_{\text {top }}-\mathrm{y}_{1, \mathrm{~b}}\right) . \\
& \Rightarrow \quad(0)^{2}=(3.4 \mathrm{~m} / \mathrm{s})^{2}+2\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\left[\mathrm{y}_{\text {top }}-(3 \mathrm{~m})\right] \\
& \Rightarrow \quad \mathrm{y}_{\text {top }}=3.59 \text { meters } \\
& \Rightarrow \mathrm{y}_{\max \text { above ground }}=\mathrm{y}_{\text {top }}+4=7.59 \text { meters } .
\end{aligned}
$$

b. and c.) Finding the time of flight $\Delta t$ and the final coordinate position $y_{\text {hit }}$ requires two equations solved simultaneously. As such, we will do both Parts $b$ and $c$ in this section.

The first thing to notice is that this is really two problems happening at the same time. During the bolt's freefall, the elevator is accelerating upward by its motor while the bolt is accelerated downward by gravity. Treating the two entities as individuals:
i.) For the elevator's motion (or, at least, the motion of the elevator's floor), assuming $y=0$ is the floor's position when the bolt releases:

$$
\begin{align*}
\mathrm{y}_{\mathrm{hit}} & =\mathrm{y}_{1, \mathrm{e}}+\mathrm{v}_{1, \mathrm{e}} \Delta \mathrm{t}+(1 / 2) \quad \mathrm{a}_{\mathrm{e}}(\Delta \mathrm{t})^{2} \\
& =(0)+(3.4 \mathrm{~m} / \mathrm{s}) \mathrm{t}+.5\left(1.5 \mathrm{~m} / \mathrm{s}^{2}\right) \mathrm{t}^{2} \tag{Equ.A}
\end{align*}
$$

ii.) For the bolt's motion, assuming that we are using the same coordinate axis as above so that the bolt's initial position is $y=3$ meters:

$$
\begin{align*}
\mathrm{y}_{\mathrm{hit}} & =\mathrm{y}_{1, \mathrm{~b}}+\mathrm{v}_{1, \mathrm{~b}} \Delta \mathrm{t}+(1 / 2) \quad \mathrm{a}_{\mathrm{b}} \quad(\Delta \mathrm{t})^{2} \\
& =(3 \mathrm{~m})+(3.4 \mathrm{~m} / \mathrm{s}) \mathrm{t}+.5\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \mathrm{t}^{2} \tag{Equ.B}
\end{align*}
$$

iii.) Equating Equations $A$ and $B$ ( $\mathrm{y}_{\mathrm{hit}}$ is the same in both equations):

$$
\begin{gathered}
(3.4 \mathrm{~m} / \mathrm{s}) \mathrm{t}+.5\left(1.5 \mathrm{~m} / \mathrm{s}^{2}\right) \mathrm{t}^{2}=3+(3.4 \mathrm{~m} / \mathrm{s}) \mathrm{t}+.5\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \mathrm{t}^{2} \\
\Rightarrow \quad 5.65 \mathrm{t}^{2}=3 \\
\Rightarrow \quad \mathrm{t}=.73 \text { seconds. }
\end{gathered}
$$

iv.) Using Equation $A$ to determine $y_{h i t}$ :

$$
\begin{aligned}
\mathrm{y}_{\mathrm{hit}} & =\mathrm{y}_{1, \mathrm{e}}+\quad \mathrm{v}_{1, \mathrm{e}} \quad \Delta \mathrm{t}+(1 / 2) \quad \mathrm{a}_{\mathrm{e}} \quad(\Delta \mathrm{t})^{2} \\
& =(0)+(3.4 \mathrm{~m} / \mathrm{s})(.73 \mathrm{~s})+.5\left(1.5 \mathrm{~m} / \mathrm{s}^{2}\right)(.73 \mathrm{~s})^{2} \\
& =2.88 \text { meters. }
\end{aligned}
$$

v.) The bolt was initially at $y=3$ meters. When it hits the floor, its coordinate is $y_{h i t}=2.88$ meters. The distance the bolt actually falls is:

$$
\begin{aligned}
\Delta \mathrm{y} & =\mathrm{y}_{\text {final }}-\mathrm{y}_{\text {initial }} \\
& =(2.88 \mathrm{~m})-(3.0 \mathrm{~m}) \\
& =-.12 \text { meters } .
\end{aligned}
$$

vi.) For the amusement of it, let's check our $y_{h i t}$ value by solving Equation B:

$$
\begin{aligned}
\mathrm{y}_{\mathrm{hit}} & =\mathrm{y}_{1, \mathrm{~b}}+\mathrm{v}_{1, \mathrm{~b}} \quad \Delta \mathrm{t}+(1 / 2) \quad \mathrm{a}_{\mathrm{b}} \quad(\Delta \mathrm{t})^{2} \\
& =(3 \mathrm{~m})+(3.4 \mathrm{~m} / \mathrm{s})(.73 \mathrm{~s})+.5\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.73 \mathrm{~s})^{2} \\
& =2.87 \text { meters. }
\end{aligned}
$$

. . . close enough for government work.
d.) The magnitude of the velocity of the bolt, relative to a fixed frame of reference (i.e., not relative to the elevator's floor) is determined as follows:

$$
\begin{aligned}
\mathrm{v}_{\mathrm{b}, \text { bot }}^{2}= & \mathrm{v}_{1, \mathrm{~b}}^{2}+2 \quad \mathrm{a}_{\mathrm{b}} \quad\left[\mathrm{y}_{\mathrm{b}, \text { bot }}-\mathrm{y}_{1, \mathrm{~b}}\right] \\
= & (3.4 \mathrm{~m} / \mathrm{s})^{2}+2\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)[(2.87 \mathrm{~m})-(3 \mathrm{~m})] \\
& \Rightarrow \mathrm{v}_{\mathrm{b}, \text { bot }}=3.76 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

As a vector, this would be $\mathbf{v}_{\mathrm{b}, \mathrm{bot}}=-(3.76 \mathrm{~m} / \mathrm{s}) \mathbf{j}$.

### 4.12)

a.) In projectile motion, questions like, "How far ( $\Delta x$ )" and "How long $(\Delta t)$ " are usually approached simultaneously. In this case, the time variable is most easily determined by looking at the motion in the $y$ direction only. Noting that the ball started at $y_{1}=1.3$ meters, ended at $y_{2}=$ 0 (i.e., at ground level), and had a $y$ component velocity of $v_{y}=41 \sin 50^{\circ}$, we can write:

$$
\begin{aligned}
\left(\mathrm{y}_{2}-\mathrm{y}_{1}\right) & =\mathrm{v}_{1, \mathrm{y}} \mathrm{t}+(1 / 2) \mathrm{a}_{\mathrm{y}} \mathrm{t}^{2} \\
(0 \mathrm{~m}-1.3 \mathrm{~m}) & =\left(41 \sin 50^{\circ}\right) \mathrm{t}+.5\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \mathrm{t}^{2} \\
-1.3 & =31.4 \mathrm{t}-4.9 \mathrm{t}^{2} \\
\Rightarrow \quad 4.9 \mathrm{t}^{2} & -31.4 \mathrm{t}-1.3=0
\end{aligned}
$$

Using the Quadratic Formula, we get:

$$
\begin{aligned}
\mathrm{t} & =\left[-\mathrm{b} \pm\left[\mathrm{b}^{2}-4 \mathrm{ac}\right]^{1 / 2}\right] / 2 \mathrm{a} \\
& =\left[-(-31.4) \pm\left[(-31.4)^{2}-4(4.9)(-1.3)\right]^{1 / 2}\right] /[2(4.9)] \\
& =[31.4 \pm(31.8)] /(9.8) \\
& =6.45 \text { seconds. }
\end{aligned}
$$

b.) Assuming $x_{1}=0$ is the $x$ coordinate at which the ball is struck, the net horizontal distance traveled will be:

$$
\begin{aligned}
& \left(\mathrm{x}_{2}-\mathrm{x}_{1}\right)=\mathrm{v}_{1, \mathrm{x}} \mathrm{t}+(1 / 2) \mathrm{a}_{\mathrm{x}} \mathrm{t}^{2} \\
& \left(\mathrm{x}_{2}-0\right)=\left(\mathrm{v}_{1} \cos \mathrm{q}\right) \mathrm{t}+.5\left(0 \mathrm{~m} / \mathrm{s}^{2}\right) \mathrm{t}^{2} \\
& \quad \Rightarrow \quad \mathrm{x}_{2}=(41 \mathrm{~m} / \mathrm{s})\left(\cos 50^{\circ}\right)(6.45 \mathrm{sec})+0 \\
& \quad=170 \text { meters. }
\end{aligned}
$$

c.) Height is a $y$ related quantity. Knowing that the $y$ component of velocity at the top of the arc (i.e., at $y_{\max }$ ) will be zero, we can write:

$$
\begin{aligned}
&\left(\mathrm{v}_{\max , \mathrm{y}}\right)^{2}=\left(\mathrm{v}_{1, \mathrm{y}}\right)^{2}+2 \mathrm{a}_{\mathrm{y}}\left(\mathrm{y}_{\max }-\mathrm{y}_{1}\right) \\
& \quad \Rightarrow \mathrm{y}_{\max }=\left[\left(\mathrm{v}_{\max , \mathrm{y}}\right)^{2}-\left(\mathrm{v}_{1, \mathrm{y}}\right)^{2}+2 \mathrm{a}_{\mathrm{y}}\left(\mathrm{y}_{1}\right)\right] / 2 \mathrm{a}_{\mathrm{y}} \\
&=\left[(0)^{2}-\left(41 \sin 50^{\circ}\right)^{2}+2\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(1.3 \mathrm{~m})\right] /\left[(2)\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\right] \\
&=51.6 \text { meters. }
\end{aligned}
$$

d.) At the end of the flight, the ball has an $x$ component of velocity that has not changed throughout the motion (we are neglecting air friction and there are no other natural forces out there to make the $x$ motion change). That value will be:

$$
\begin{aligned}
\mathrm{v}_{2, \mathrm{x}} & =(41 \mathrm{~m} / \mathrm{s})\left(\cos 50^{\circ}\right) \\
& =26.4 \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

The $y$ motion velocity has changed because gravity has been accelerating the ball throughout the motion. We can get the $y$ velocity using:

$$
\begin{aligned}
& \left(\mathrm{v}_{2, \mathrm{y}}\right)^{2}=\left(\mathrm{v}_{1, \mathrm{y}}\right)^{2}+2 \mathrm{a}_{\mathrm{y}}\left(\mathrm{y}_{2}-\mathrm{y}_{1}\right) \\
\Rightarrow \quad \mathrm{v}_{2, \mathrm{y}}= & {\left[\left(\mathrm{v}_{1, \mathrm{y}}\right)^{2}+2 \mathrm{a}_{\mathrm{y}}\left(\mathrm{y}_{2}-\mathrm{y}_{1}\right)\right]^{1 / 2} } \\
= & {\left[\left[(41 \mathrm{~m} / \mathrm{s})\left(\sin 50^{\circ}\right)\right]^{2}+2\left(-9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(0-1.3 \mathrm{~m})\right]^{1 / 2} } \\
= & 31.8 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

Note: This equation yields magnitudes only. The $y$ component of the "final" velocity is in the $-\boldsymbol{j}$ direction. That means $v_{2, y}=-31.8 \mathrm{~m} / \mathrm{s}$.

Putting it all together:

$$
\mathbf{v}_{2}=(26.4 \mathbf{i}-31.8 \mathbf{j}) \mathrm{m} / \mathrm{s}
$$
