## CHAPTER 5 -- NEWTON'S LAWS

5.1) Drawing a free body diagram for the force of EACH BODY in each sketch:
a.)

b.)

Note 1: There are two action/reaction force pairs between masses $A$ and $B$ : the normal force $N_{b l B}$ that $A$ applies to $B$ and vice versa, and the frictional force $f$ between the two. Be sure you understand what is going on here!

Note 2: Notice that the magnitude of the tension force $T$ on mass $C$ and mass $B$ is the same.

Note 3: The pulley mount on mass $A$ applies a downward and to the left force $F_{\text {pulley }}$ on mass $A$. As we are interested in ALL the forces acting on each mass, that force has to be included.
c.)

d.)

Note 1: All the pulleys do here is redirect the line of the tension $T$.

Note 2: The pin that holds each pulley in place must exert a force that
effectively

keeps its pulley from flying off into space.

## Note 3:

There is a
force acting at the pin of each pulley to keep the pulleys from falling through the table.
5.2) According to Newton's Third Law:
a.) The reaction to the force the floor applies to you is the force you apply to the floor.
b.) The reaction to the force a string applies to a weight is the force the weight applies to the string.
c.) The reaction to the force a car applies to a tree is the force the tree applies to the car.
d.) The reaction to the force the earth applies to the moon is the force the moon applies to the earth.

## 5.3)

a.) A free body diagram for the situation before your friend applies his force (Part $B$ ) is shown below. Making $a_{x}$ into a MAGNITUDE by unembedding the negative sign, N.S.L. yields:

$$
\begin{aligned}
& \sum F_{x}: \\
&-f_{k}=-m a_{x} \\
& \Rightarrow \quad-(12 \mathrm{nt})=-(30 \mathrm{~kg}) a \\
& \Rightarrow \quad a=.4 \mathrm{~m} / \mathrm{s}^{2} .
\end{aligned}
$$

Note 1: Why make $a_{x}$ into a magnitude by unembedding the negative sign? In certain kinds of problems, doing so will make life easier. Get used to it.

Note 2: In the next question, you are going to need $\mu_{k}$. From the f.b.d. above, $N=m g=(30 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)=294 \mathrm{nts}$. As $f_{k}=\mu_{k} N$, we can write $\mu_{k}=f_{k} / N$ $=(12 n t) /(294 n t)=.04$.
b.) With the additional force applied by your friend, the free body diagram looks like the one shown to the right (note that $N$ has changed). To determine $N$ :

$$
\begin{aligned}
& \frac{\sum \mathrm{F}_{\mathrm{y}}:}{\mathrm{N}+\mathrm{F} \sin } 40^{\circ}-\mathrm{mg}=-\mathrm{ma}_{\mathrm{y}} \quad\left(=0 \text { as } a_{y}=0\right) \\
& \Rightarrow \quad \mathrm{N}
\end{aligned} \begin{aligned}
& =-\mathrm{F} \sin 40^{\circ}+\mathrm{mg} \\
& =-(60 \mathrm{nt}) \sin 40^{\circ}+(30 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \\
& =255 \mathrm{nts} .
\end{aligned}
$$

with friction with friend's force

$$
\frac{\sum F_{x}:}{-\mu_{k} N+F \cos 40^{\circ}=-m a_{x} .}
$$

Note 1: In this case, I have assumed that your friend's force will not overcome that of friction and the direction of the sled's acceleration will still be negative (i.e., to the left). As such, I have unembedded the negative sign in front of the $m a$ term. If I am wrong, the SIGN of the calculated acceleration will be negative. Continuing:

$$
\begin{aligned}
& -\mu_{\mathrm{k}} \mathrm{~N}+\mathrm{F} \cos 40^{0}=-m a_{\mathrm{x}} \\
& \quad \Rightarrow-(.04)(255 \mathrm{nt})+(60 \mathrm{nt})(.766)=-(30 \mathrm{~kg}) \mathrm{a} \\
& \quad \Rightarrow \quad a=-1.19 \mathrm{~m} / \mathrm{s}^{2} .
\end{aligned}
$$

Note 2: The negative sign means that I've assumed the wrong direction for a. Evidently, your friend's force was greater than the frictional force and the acceleration was really in the $+x$ direction (if this ever happens to you, what I've just said is all you will have to state to make the problem OK).
c.) The graph of $F(\phi)$ vs. $\phi$ looks something like the graph shown in the figure to the right. Notice that at the minimum, the slope of $F(\phi)$ is ZERO (that is, $d F(\phi) / d \phi=0$ at that point). All we have to do is generate an expression for the force as a function of $\phi$, then put its derivative equal to zero and solve for $\phi$ under
 that condition. That will produce the angle at which the force is a minimum.

Executing that operation:
i.) The f.b.d for the situation is shown to the right.
ii.) Noting that we will need to use
 $\mu_{k} N$ for the frictional force $f_{k}$, we will start with N.S.L. in the $y$ direction to determine $N$ :

$$
\begin{aligned}
& \quad \frac{\sum \mathrm{F}_{\mathrm{y}}:}{} \mathrm{N}+\mathrm{F} \sin \phi-\mathrm{mg}=\mathrm{ma}_{\mathrm{y}} \\
& \quad=0 \quad\left(\text { as } a_{y}=0\right) \\
& \Rightarrow \quad \mathrm{N}=-\mathrm{F} \sin \phi+\mathrm{mg}
\end{aligned}
$$

(Equation A).
iii.) Using N.S.L. in the $x$ direction, we get:

$$
\begin{aligned}
& \sum \mathrm{F}_{\mathrm{x}}: \\
&-\mu_{\mathrm{k}} \mathrm{~N}+\mathrm{F} \cos \phi=\operatorname{ma}_{\mathrm{x}} \\
&=0 \text { (as the velocity is constant). }
\end{aligned}
$$

iv.) Substituting Equation $A$ into this expression yields:

$$
\begin{aligned}
& -\mu_{\mathrm{k}}(-\mathrm{F} \sin \phi+\mathrm{mg})+\mathrm{F} \cos \phi=0 \\
& \quad \Rightarrow \quad \mathrm{~F}=\left[\mu_{\mathrm{k}} \mathrm{mg}\right] /\left[\mu_{\mathrm{k}} \sin \phi+\cos \phi\right]
\end{aligned}
$$

v.) Given that the body is moving with a constant velocity (i.e., it isn't accelerating), we now have a function that defines the force applied in terms of the angle of the force. Taking the derivative of that function and setting it equal to zero yields an expression from which the angle of minimum force can be determined. Using the Chain Rule to determine the expression, we get:

$$
\begin{aligned}
\frac{\mathrm{dF}(\phi)}{\mathrm{d} \phi} & =\frac{\mathrm{d}\left[\frac{\mu_{\mathrm{k}} \mathrm{mg}}{\mu_{\mathrm{k}}(\sin \phi)+\cos \phi}\right]}{\mathrm{d} \phi} \\
& =\frac{\mathrm{d}\left[\mu_{\mathrm{k}} \mathrm{mg}\left[\mu_{\mathrm{k}}(\sin \phi)+\cos \phi\right]^{-1}\right]}{\mathrm{d} \phi} \\
& =\mu_{\mathrm{k}} \mathrm{mg}(-1)\left[\mu_{\mathrm{k}}(\sin \phi)+\cos \phi\right]^{-2}\left[\mu_{\mathrm{k}}(\cos \phi)-\sin \phi\right] \\
& =\frac{-\mu_{\mathrm{k}} \mathrm{mg}\left[\mu_{\mathrm{k}}(\cos \phi)-\sin \phi\right]}{\left[\mu_{\mathrm{k}}(\sin \phi)+\cos \phi\right]^{2}}
\end{aligned}
$$

vi.) As ungodly as this may look, the criterion for this expression equaling zero is relatively simple. All that must be true is that the numerator equal zero. That will be satisfied if $\mu_{k}(\cos \phi)-(\sin \phi)=0$. With that observation:

$$
\begin{aligned}
& \mu_{\mathrm{k}}(\cos \phi)-(\sin \phi)=0 \\
& \quad \Rightarrow \quad \mu_{\mathrm{k}}=[\sin \phi] /[\cos \phi]
\end{aligned}
$$

vii.) As $\sin (\phi) / \cos (\phi)=\tan \phi$, we can write:

$$
\phi=\tan ^{-1}\left(\mu_{\mathrm{k}}\right)
$$

This is the optimal angle at which the force $F$ will be a minimum.

## 5.4)

a.) A stationary elevator will feel no friction; the f.b.d. for the situation is shown in the sketch to the right. Using N.S.L.:

$$
\begin{aligned}
& \frac{\sum \mathrm{F}_{\mathrm{y}}:}{\mathrm{T}-\mathrm{mg}}= \\
& =\mathrm{ma} \\
& \quad=0 \quad\left(\text { as elevator's acc. } a_{e}=0\right) \\
& \Rightarrow \quad \mathrm{T}
\end{aligned} \quad \begin{aligned}
& \mathrm{mg} \\
&=(400 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \\
&=3920 \mathrm{nts} .
\end{aligned}
$$

b.) With the upward acceleration of the elevator, the frictional force will be applied downward as shown in the f.b.d. to the right. The acceleration term $a$ is a magnitude whose sign (manually placed) is positive. N.S.L. yields:

$$
\begin{aligned}
& \frac{\sum \mathrm{F}_{\mathrm{y}}:}{\qquad \mathrm{T}-\mathrm{mg}-\mathrm{f}_{\mathrm{k}}=+\mathrm{ma}} \\
& \qquad \begin{aligned}
\Rightarrow \quad \mathrm{T} & =\mathrm{mg}+\mathrm{f}_{\mathrm{k}}+\mathrm{ma} \\
& =(400 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)+(80 \mathrm{nt})+(400 \mathrm{~kg})\left(2.8 \mathrm{~m} / \mathrm{s}^{2}\right) \\
& =5120 \mathrm{nts} .
\end{aligned}
\end{aligned}
$$

c.) The only difference between this problem and Part $b$ is that the acceleration is zero (constant velocity means zero acceleration). It makes no difference what the velocity actually is; the forces acting on the elevator are the same as in Part bo the f.b.d. from Part b is still valid. Using it, we get:

$$
\begin{aligned}
& \quad \frac{\sum F_{y}:}{} \quad \begin{aligned}
\mathrm{T}-\mathrm{mg}-\mathrm{f}_{\mathrm{k}} & =m a \\
\Rightarrow \quad \mathrm{~T} & =m g+\mathrm{f}_{\mathrm{k}}+\mathrm{m}(0) \\
\Rightarrow \quad & =(400 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)+(80 \mathrm{nt}) \\
& =4000 \mathrm{nts} .
\end{aligned}
\end{aligned}
$$

d.) With the downward velocity, friction is upward as shown in the f.b.d. to the right. N.S.L. yields:

$$
\begin{aligned}
& \frac{\sum \mathrm{F}_{\mathrm{y}}:}{\mathrm{T}-\mathrm{mg}}+\mathrm{f}_{\mathrm{k}}=-\mathrm{ma} \\
& \Rightarrow \mathrm{~T}
\end{aligned} \begin{aligned}
& \mathrm{mg}-\mathrm{f}_{\mathrm{k}}-\mathrm{ma} \\
&=(400 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)-(80 \mathrm{nt})-(400 \mathrm{~kg})\left(2.8 \mathrm{~m} / \mathrm{s}^{2}\right) \\
&=2720 \mathrm{nts} .
\end{aligned}
$$

Note: Whenever you can, make the acceleration term $a$ a magnitude. That is what I've done above (the acceleration's negative sign has been unembedded). Be careful when you do this, though. Don't put a negative sign in front of the $a$, then proceed to use $-2.8 \mathrm{~m} / \mathrm{s}^{2}$ when it comes time to put in the numbers.
e.) Moving with a constant velocity means that the acceleration $a$ is zero. Friction is still acting (upward in this case), so the f.b.d. used in Part $d$ is still valid (the forces haven't changed, there is just no acceleration).

$$
\begin{aligned}
& \quad \frac{\sum F_{y}:}{} \quad \begin{aligned}
& \mathrm{T}-\mathrm{mg}+\mathrm{f}_{\mathrm{k}}=-\mathrm{ma} \\
& \Rightarrow \mathrm{~T}=\mathrm{mg}-\mathrm{f}_{\mathrm{k}}-\mathrm{m}(0) \\
&=(400 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)-(80 \mathrm{nt}) \\
&=3840 \mathrm{nts} .
\end{aligned}
\end{aligned}
$$

5.5) The scale in this case is measuring the net force you apply to the scale (or the ground). If the acceleration is upward, this force $F_{\text {scale }}$ will be greater than $m g$; if downward, it will be less than $m g$. To determine the acceleration direction, we need to determine $m g$ :

$$
\begin{aligned}
\mathrm{mg} & =(60 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \\
& =588 \text { newtons } .
\end{aligned}
$$

As this is less than the scale reading of 860 newtons, the elevator must be accelerating upward and the acceleration's sign must be positive.

By Newton's Third Law, the force you apply to the scale must be equal and opposite the force the scale applies to you. As such, using an f.b.d. and N.S.L. on yourself (see to right) yields:

$$
\begin{aligned}
& \sum \mathrm{F}_{\mathrm{y}}: \\
& \mathrm{F}_{\text {scale }}-\mathrm{mg} \\
& \qquad \begin{aligned}
& \Rightarrow \mathrm{ma} \\
& \Rightarrow \quad=\left(\mathrm{F}_{\text {scale }} / \mathrm{m}\right)-\mathrm{g} \\
&=(860 \mathrm{nt}) /(60 \mathrm{~kg})-\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \\
&=4.53 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
\end{aligned}
$$

Note: If we had assumed a downward acceleration (i.e., an acceleration that was negative), we would have gotten a negative sign in front of the calculated $a$ term above. The negative sign in an answer like that does not identify direction. By unembedding the sign, we have made the acceleration term a magnitude. As such, it should be positive. The negative sign in front of an answer in such instances means we have assumed the wrong direction for the acceleration, nothing else!

## 5.6)

a.) An f.b.d. for the forces on the mass is shown to the right. Noting that the acceleration is to the right, I have put one coordinate axis along the horizontal. N.S.L. in the $x$ direction yields:

$$
\begin{aligned}
& \underline{\sum F_{\mathrm{x}}}: \\
& \quad \mathrm{T} \sin \theta=\mathrm{ma} \\
& \quad \Rightarrow \quad \mathrm{a}=(\mathrm{T} \sin \theta) / \mathrm{m} \quad \text { (Equation } \mathrm{A}) .
\end{aligned}
$$

We need to determine $T$ to solve this. Using N.S.L. in the $y$ direction yields:

$$
\begin{aligned}
\frac{\sum \mathrm{F}_{\mathrm{y}}:}{\mathrm{T} \cos \theta-\mathrm{mg}} & =\mathrm{ma}_{\mathrm{y}} \\
& =0 \quad\left(\operatorname{as} a_{y}=0\right) \\
\Rightarrow & \mathrm{T}=\mathrm{mg} /(\cos \theta)
\end{aligned}
$$

Re-writing, then substituting back into Equation A yields:

$$
\begin{aligned}
\mathrm{a} & =[\mathrm{T}](\sin \theta) / \mathrm{m} \\
& =[\mathrm{mg} /(\cos \theta)](\sin \theta) / \mathrm{m} .
\end{aligned}
$$

The $m$ 's cancel and $(\sin \theta) /(\cos \theta)$ is $\tan \theta$, so we end up with

$$
\mathrm{a}=\mathrm{g} \tan \theta
$$

For our problem, the numbers yield:

$$
\begin{aligned}
\mathrm{a} & =\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\left(\tan 26^{\circ}\right) \\
& =4.78 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
$$

b.) At constant velocity, there is no acceleration and, hence, no swing observed. The string and mass should hang completely vertical. Note: That is exactly what the equation in the $x$ direction suggests. The only time the acceleration will equal zero in $T \sin \theta=m a$ is when $\theta=0$.

Note: One intrepid student whose father was a pilot pointed out that airplane floors (and ceilings) are not horizontal (she observed that when she walks to the bathroom at the rear of a plane, she always walks down hill). In any case, that idiosyncracy isn't important here as the angle is measured relative to the vertical.

## 5.7)

a.) We are interested in finding the coefficient of static friction between both $m_{1}$ and $m_{2}\left(\right.$ call this $\left.\mu_{s, 1}\right)$ and between $m_{2}$ and the wall (call this $\mu_{s, 2}$ ), when $F=$ 25 newtons.
--To the right is the f.b.d. for $m_{1}$. N.S.L. yields:

$$
\begin{aligned}
& \underline{\sum F_{x}:} \begin{aligned}
\mathrm{F}-\mathrm{N}_{1} & =\mathrm{m}_{1} \mathrm{a}_{\mathrm{x}} \\
= & \quad\left(\text { as } \mathrm{a}_{\mathrm{x}}=0\right)
\end{aligned} \\
& \left.\Rightarrow \quad \mathrm{N}_{1}=\mathrm{F} \quad \text { (equal to } 25 \mathrm{nts}\right)
\end{aligned} \quad \begin{array}{r}
\sum \mathrm{F}_{\mathrm{y}}: \\
\mu_{\mathrm{s}, 1} \mathrm{~N}_{1}-\mathrm{m}_{1} \mathrm{~g}=\mathrm{m}_{1} \mathrm{a}_{1} \\
=0 \quad\left(\text { as } a_{1}=0\right) \\
\Rightarrow \quad \mu_{\mathrm{s}, 1}=\left(\mathrm{m}_{1} \mathrm{~g}\right) / \mathrm{N}_{1}
\end{array}
$$

$$
\begin{aligned}
& =\left[(2 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\right] /(25 \mathrm{nt}) \\
& =.784 \quad \text { (note that the coefficient is unitless). }
\end{aligned}
$$

--The f.b.d. for $m_{2}$ is shown to the right. A number of observations need to be made before dealing with N.S.L.:
i.) Look at $m_{1}$ 's f.b.d. on the previous page. Notice that it experiences a normal force $N_{1}$ due to its being jammed up against $m_{2}$. As such, $m_{2}$ must feel a reaction force (Newton's Third Law) of the same magnitude (i.e., $N_{1}$ ) in the opposite direction. That force has been placed on f.b.d. on mass $\mathrm{m}_{2}$ $m_{2}$ 's f.b.d.
ii.) Look again at $m_{1}$ 's f.b.d. on the previous page. Notice that it experiences a frictional force $f_{s, 1}$ due to its rubbing up against $m_{2}$. As such, $m_{2}$ must feel a reaction force of magnitude $f_{s, 1}$ in the direction opposite that of the frictional force on $m_{1}$. That force has been placed on $m_{2}{ }^{\prime} s$ f.b.d.
iii.) Having made those observations, N.S.L. yields:

$$
\begin{aligned}
& \underline{\sum F_{x}}: \\
& \mathrm{N}_{1}-\mathrm{N}_{2}=\mathrm{m}_{2} \mathrm{a}_{\mathrm{x}} \\
& =0 \quad\left(\text { as } a_{x}=0\right) \\
& \Rightarrow \quad \mathrm{N}_{1}=\mathrm{N}_{2} \text { (equal to } F=25 \mathrm{nts} \text { as } N_{1}=F \text { ). } \\
& \underline{\sum F_{y}}: \\
& \mu_{\mathrm{s}, 2} \mathrm{~N}_{2}-\mu_{\mathrm{s}, 1} \mathrm{~N}_{1}-\mathrm{m}_{2} \mathrm{~g}=\mathrm{m}_{2} \mathrm{a}_{2} \\
& =0 \quad\left(\operatorname{as} \alpha_{2}=0\right) \\
& \Rightarrow \quad \mu_{\mathrm{s}, 2}=\left[\mu_{\mathrm{s}, 1} \mathrm{~N}_{1}+\mathrm{m}_{2} \mathrm{~g}\right] / \mathrm{N}_{2} \\
& =\left[(.784)(25 \mathrm{nt})+(7 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\right] /(25 \mathrm{nt}) \\
& =3.528 \text {. }
\end{aligned}
$$

b.) The force $F$ is now 20 newtons. That means there is not enough force associated with $F$ to keep the bodies pinned to the wall. That being the case, they begin to accelerate downward. Assume the coefficients of kinetic friction are $\mu_{k, 1}=.15$ and $\mu_{k, 2}=.9$ respectively.

As innocuous as this scenario may seem, the problem has the potential to be a real stinker. Why? Because the direction of a frictional force on a body depends upon the direction of its slide relative to the other body. We don't know the acceleration of each of the bodies. We do know that if $m_{2}$ accelerates downward faster than $m_{1}$, then $m_{1}$ 's motion relative to $m_{2}$ will be upward and the frictional force on $m_{1}$ will be downward. If $m_{2}$ accelerates downward more slowly than $m_{1}$, then $m_{1}$ 's motion relative to $m_{2}$ will be downward and the frictional force on $m_{1}$ will be upward. Not knowing the acceleration of either body means we don't know which body will be moving faster and, hence, what direction the frictional force will be on either object. In short, we have to do the problem both ways to see which ends up making sense.

We will start by assuming $m_{1}$ accelerates faster than $m_{2}$. In that case, the frictional force on $m_{1}$ will be upward and the f.b.d. for the situation will be as shown to the right. Using N.S.L.

f.b.d. on mass $\mathrm{m}_{1}$ on $m_{1}$, we get:

$$
\begin{aligned}
& \frac{\sum \mathrm{F}_{\mathrm{x}}:}{\mathrm{F}-\mathrm{N}_{1}=} \begin{aligned}
=\mathrm{m}_{1} \mathrm{a}_{\mathrm{x}} \\
=0 \quad\left(\text { as } \mathrm{a}_{\mathrm{x}}=0\right)
\end{aligned} \\
& \left.\Rightarrow \quad \quad \mathrm{F}=\mathrm{N}_{1} \quad \text { (equal to } 20 \mathrm{nt}\right)
\end{aligned} \quad \begin{aligned}
\begin{aligned}
& \sum \mathrm{F}_{\mathrm{y}}: \\
& \mu_{\mathrm{k}, 1} \mathrm{~N}_{1}-\mathrm{m}_{1} \mathrm{~g}=-\mathrm{m}_{1} \mathrm{a}_{1} . \\
& \Rightarrow \quad \mathrm{a}_{1}=\left[-\mu_{\mathrm{k}, 1} \mathrm{~N}_{1}+\mathrm{m}_{1} \mathrm{~g}\right] / \mathrm{m}_{1} \\
&=\left[-(.15)(20 \mathrm{nt})+(2 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\right] /(2 \mathrm{~kg}) \\
&=8.3 \mathrm{~m} / \mathrm{s}^{2} .
\end{aligned}
\end{aligned}
$$

--The f.b.d. for the forces acting on $m_{2}$ are shown on the next page. N.S.L. yields:

$$
\begin{aligned}
& \underline{\sum F_{y}:} \\
& \mu_{k, 2} N_{2}-\mu_{k, 1} N_{1}-m_{2} g=-m_{2} a_{2} \\
& \Rightarrow \quad \mathrm{a}_{2}=\left[-\mu_{\mathrm{k}, 2} \mathrm{~N}_{2}+\mu_{\mathrm{k}, 1} \mathrm{~N}_{1}+\mathrm{m}_{2} \mathrm{~g}\right] / \mathrm{m}_{2} \\
& =\left[-(.9)(20 \mathrm{nt})+(.15 \mathrm{~kg})(20 \mathrm{nt})+(7 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\right] /(7 \mathrm{~kg}) \\
& =7.66 \mathrm{~m} / \mathrm{s}^{2} \text {. }
\end{aligned}
$$

Note 1: Yes! We've lucked out. We assumed $m_{1}$ accelerates faster than $m_{2}$, and that is just what our calculations have verified. If we had been wrong, we would have gotten senseless results. As we got it right on the first try, we needn't go further.

Note 2: For the amusement of it, let's go further. That is, assume that $m_{1}$ accelerates more slowly than $m_{2}$. That means $m_{1}$ will slide upward relative to $m_{2}$ and the frictional force will be downward (this is exactly opposite the situation we outlined above). With the direction of the frictional force reversed, the f.b.d. on $m_{1}$ look as shown to the right. N.S.L. yields:

$$
\begin{aligned}
& \sum \mathrm{F}_{\mathrm{x}}: \\
& \mathrm{F}-\mathrm{N}_{1}=\mathrm{m}_{1} \mathrm{a}_{\mathrm{x}} \\
&=0 \quad\left(\mathrm{as} a_{x}=0\right) \\
& \Rightarrow \quad \mathrm{F}=\mathrm{N}_{1} \quad(=20 \mathrm{nts})
\end{aligned}
$$

$$
\begin{aligned}
& \sum \mathrm{F}_{\mathrm{y}}: \\
& \qquad \begin{aligned}
-\mu_{\mathrm{k}, 1} \mathrm{~N}_{1}-\mathrm{m}_{1} \mathrm{~g} & =-\mathrm{m}_{1} \mathrm{a}_{1} \\
\Rightarrow \quad \mathrm{a}_{1} & =\left[\mu_{\mathrm{k}, 1} \mathrm{~N}_{1}+\mathrm{m}_{1} \mathrm{~g}\right] / \mathrm{m}_{1} \\
& =\left[(.15)(20 \mathrm{nt})+(2 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\right] /(2 \mathrm{~kg}) \\
& =11.3 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
\end{aligned}
$$

Yikes! According to our calculations, block $m_{1}$ is accelerating faster than the acceleration of gravity ( $g=9.8 \mathrm{~m} / \mathrm{s}^{2}$ ). That isn't possible in this situation. Conclusion? We made bad assumptions about the acceleration of $m_{1}$ and $m_{2}$.
c.) The reason the accelerations are different? They have different forces acting on them!

## 5.8)

a.) The free body diagrams for this situation are shown to the right.
b.) We need the frictional forces in both cases, which means we need both $N_{1}$ and $N_{2}$. Using N.S.L. in the $y$ direction:

$$
\begin{aligned}
& \underline{\sum F_{y}:} \\
& \quad \mathrm{N}_{1}-\mathrm{m}_{1} \mathrm{~g} \cos \theta=\mathrm{m}_{1} \mathrm{a}_{\mathrm{y}} \\
& \Rightarrow \quad \mathrm{~N}_{1}=\mathrm{m}_{1} \mathrm{~g} \cos \theta \quad\left(\text { as } a_{y}=0\right) .
\end{aligned}
$$

Likewise, $N_{2}=m_{2} g \cos \theta$.
--Using N.S.L. for the $x$-motion of $m_{1}$, noting that the acceleration is in the negative direction, relative to our coordinate axis (the body is slowing, hence the acceleration is opposite the direction of the velocity):

$$
\underline{ }_{\underline{F_{x}}:}^{T}-\mu_{\mathrm{k}} \mathrm{~N}_{1}-\mathrm{m}_{1} \mathrm{~g} \sin \theta=-\mathrm{m}_{1} \mathrm{a} .
$$

Substituting in for $N_{1}$ and solving for $m_{1} a$, we get:

$$
\left.m_{1} \mathrm{a}=\left[-\mathrm{T}+\mu_{\mathrm{k}}\left(\mathrm{~m}_{1} \mathrm{~g} \cos \theta\right)+\mathrm{m}_{1} \mathrm{~g} \sin \theta\right] \quad \text { (Equation } A\right) .
$$

--To get rid of the tension term, consider the $x$ motion of $m_{2}$ :

$$
\frac{\sum F_{x}:}{-T-\mu_{k} N_{2}-m_{2} g \sin \theta=-m_{2} a . ~}
$$

Substituting in for $N_{2}$ and solving for the tension $T$, we get:

$$
\mathrm{T}=-\mu_{\mathrm{k}}\left(\mathrm{~m}_{2} \mathrm{~g} \cos \theta\right)-\mathrm{m}_{2} \mathrm{~g} \sin \theta+\mathrm{m}_{2} \mathrm{a}
$$

Substituting the tension term into Equation A yields:

$$
m_{1} a=\left[-\left(-\mu_{k}\left(m_{2} g \cos \theta\right)-m_{2} g \sin \theta+m_{2} a\right)+\mu_{k}\left(m_{1} g \cos \theta\right)+m_{1} g \sin \theta\right]
$$

Solving for the acceleration yields:

$$
\begin{aligned}
a & =\left[\mu_{k}\left(m_{2} g \cos \theta\right)+m_{2} g \sin \theta+\mu_{k}\left(m_{1} g \cos \theta\right)+m_{1} g \sin \theta\right] /\left(m_{1}+m_{2}\right) \\
& =\mu_{k} g \cos \theta+g \sin \theta .
\end{aligned}
$$

c.) Plugging the expression for $a$ back into Equation $A$ allows us to determine $T$. I'll save space by leaving the exercise to you.
5.9) This is an important situation because it requires you to face all the pitfalls that can occur when doing incline-plane problems.

We know $m_{1}$ is moving down the incline. That means $m_{2}$ is moving upward. Unfortunately, we have not been told the direction of acceleration for either $m_{1}$ or $m_{2}$.
 For the sake of amusement, let's assume $m_{1}$ 's acceleration is $u p$ the incline (i.e., it's slowing). That will make $m_{2}{ }^{\prime} s$ acceleration (remember, it's physically moving upward) downward (i.e., it's also slowing). Consider $m_{2}$ 's f.b.d. first. N.S.L. allows us to write:

\[

\]

Remembering that the magnitude of $m_{1}$ 's acceleration is numerically equal to $a_{2} \cos \theta$ (this was pointed out in the original set-up), now consider $m_{1}$ 's f.b.d. N.S.L. yields:

$$
\begin{aligned}
& \underline{\sum F_{x}:} \\
& \quad \mathrm{T} \cos \phi+\mu_{\mathrm{k}} \mathrm{~N}-\mathrm{m}_{1} \mathrm{~g} \sin \theta=\mathrm{m}_{1} \mathrm{a}_{1} \\
& \Rightarrow \quad \mathrm{~T} \cos \phi+\mu_{\mathrm{k}} \mathrm{~N}-\mathrm{m}_{1} \mathrm{~g} \sin \theta=\mathrm{m}_{1}\left(\mathrm{a}_{2} \cos \theta\right)
\end{aligned}
$$

(Equation 2).

At this point, we have three unknowns $N, a$, and $T$. To determine an expression for $N$, consider N.S.L. in the $y$ direction for $m_{1}$. Doing so yields:

$$
\begin{aligned}
& \sum \mathrm{F}_{\mathrm{y}}: \\
& \quad \mathrm{T} \sin \phi+\mathrm{N}-\mathrm{m}_{1} \mathrm{~g} \cos \theta=\mathrm{m}_{1} \mathrm{a}_{\mathrm{y}}=0
\end{aligned} \quad \text { (as } a_{y}=0 \text { ) }
$$

--Note that although the problem did not ask you to do so, solving for $a_{2}$ is done in the following manner.

Plugging Equation 1 into Equation 3 yields:

$$
N=-\left(m_{2} g-m_{2} a_{2}\right) \sin \phi+m_{1} g \cos \theta
$$

(Equation 4)

Plugging Equation 1 and Equation 4 into Equation 2 yields:

$$
\begin{array}{ccc}
\mathrm{T} & \cos \phi+\mu_{k} & \mathrm{~N} \\
\left(\mathrm{~m}_{2} \mathrm{~g}-\mathrm{m}_{2} \mathrm{a}_{2}\right) \cos \phi+\mu_{\mathrm{k}}\left[-\left(\mathrm{m}_{2} \mathrm{~g}-\mathrm{m}_{2} \mathrm{a}_{2}\right) \sin \phi+\mathrm{m}_{1} \mathrm{~g} \cos \theta-\mathrm{m}_{1} \mathrm{~g} \sin \theta=\mathrm{m}_{1}\left(\mathrm{a}_{2} \cos \phi\right)\right. \\
\left(\mathrm{a}_{2} \cos \phi\right)
\end{array}
$$

Rearranging and solving for $\mathrm{a}_{2}$ yields:

$$
a_{2}=\frac{m_{2} g \cos \phi-\mu_{k} m_{2} g \sin \phi+\mu_{k} m_{1} g \cos \theta-m_{1} g \sin \theta}{m_{1} \cos \phi+m_{2} \cos \phi-\mu_{k} m_{2} \sin \phi}
$$

Interesting Note: There are positive and negative parts of the denominator, but it's OK because the two amounts will never add to zero.
5.10) This is a circular motion problem. There must be a natural force somewhere in the system that acts to change the direction of $m_{1}$ 's motion. That is, there must be a gravitational or normal or tension or friction or push-me-pull-you force that is center-seeking. In this case, that force provided by the system is the tension in the string. The

problem proceeds:
Using N.S.L. on mass $m_{1}$ (see f.b.d. to right):

$$
\begin{aligned}
& \sum \mathrm{F}_{\mathrm{c}}: \\
&-\mathrm{T}=-\mathrm{m}_{1} \mathrm{a}_{\mathrm{c}} \\
& \Rightarrow \mathrm{~T}=\mathrm{m}_{1}\left(\mathrm{v}^{2} / \mathrm{R}\right) \\
& \Rightarrow \mathrm{v}=\left(\mathrm{TR} / \mathrm{m}_{1}\right)^{1 / 2}
\end{aligned}
$$

This equation has two unknowns, $v$ and $T$. To get rid of the tension term, consider N.S.L. applied to mass $m_{2}$ (see f.b.d. to right):

$$
\begin{aligned}
& \frac{\sum \mathrm{F}_{\mathrm{v}}:}{\mathrm{T}}-\mathrm{m}_{2} \mathrm{~g}=0 \quad\left(\text { as } a_{y}=0\right) \\
& \quad \Rightarrow \mathrm{T}=\mathrm{m}_{2} \mathrm{~g} .
\end{aligned}
$$

Substituting back into our expression for $v$, we get:

$$
\begin{aligned}
\mathrm{v} & =\left[\mathrm{TR} / \mathrm{m}_{1}\right]^{1 / 2} \\
& =\left[\left(\mathrm{m}_{2} \mathrm{~g}\right) \mathrm{R} / \mathrm{m}_{1}\right]^{1 / 2} .
\end{aligned}
$$

This is a nice problem as it requires you to deal with more than one body. The approach is the same as it has always been. Do an f.b.d. for one body in the system. In this case, notice that the body is moving in a circular path. As such, orient one axis so that it is center-seeking (i.e., along the radius of the arc upon which the bob is moving). Use N.S.L. to generate as many equations as needed. If you haven't enough equations to solve for the desired unknown, pick a second mass and repeat the approach.
5.11) An f.b.d. for the forces acting on the cart when at the top of the loop is shown to the right. N.S.L. yields:

When the cart just freefalls through the top of the arc, the normal force goes to zero. In that case:

$$
\mathrm{v}=[\mathrm{gR}]^{1 / 2} .
$$

### 5.12)

a.) To begin with, the tension vector must have a vertical component (see f.b.d. to the right). If it doesn't, there will be nothing to counteract gravity and the rock must accelerate downward-something our object is not doing. As such, that vertical force will ALWAYS equal $m g$. BUT, if the rock is moving fast, the angle will be small and the vertical component will be very small in comparison to $T$. In that case, we can assume the tension force $T$ is wholly centripetal and $r=L$. Using those assumptions:

$$
\begin{aligned}
& \underline{\sum \mathrm{F}_{\mathrm{c}}:} \\
& \mathrm{T}
\end{aligned}=\mathrm{m} \mathrm{a} \mathrm{c}_{\mathrm{c}} .
$$

Putting in the numbers and using $T_{\max }$, this yields:

$$
\begin{aligned}
\mathrm{v} & =[\mathrm{TL} / \mathrm{m}]^{1 / 2} \\
& =[(50 \mathrm{nt})(1.2 \mathrm{~m}) /(.2 \mathrm{~kg})]^{1 / 2} \\
& =17.32 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

b) Because there is centripetal motion going on here, the temptation is to draw an f.b.d. like the one shown to the right and then sum the forces in the center-seeking direction. Noting that the radius $r$ of the body's motion is $L \cos \theta$, we write:

$$
\begin{aligned}
\frac{\sum \mathrm{F}_{\mathrm{c}}:}{\mathrm{T}} \cos \theta & =\mathrm{m} \mathrm{a} \\
& =\mathrm{m}\left[\mathrm{v}^{2} / \mathrm{r}\right] \\
& =\mathrm{m}\left[\mathrm{v}^{2} /(\mathrm{L} \cos \theta)\right] \\
\Rightarrow & (\cos \theta)^{2}=\left[\mathrm{mv}^{2} / \mathrm{LT}\right] .
\end{aligned}
$$

This equation would be great if we knew the velocity and wanted the angle (or vice versa). Unfortunately, we know neither. In other words, for this particular question, summing in the center-seeking direction is going to be no help at all (at least not initially). With that in mind, let's use N.S.L. in the vertical direction and pray it gives us an equation we can use.

$$
\begin{aligned}
& \underline{\sum \mathrm{F}_{\mathrm{v}}:} \\
& \begin{aligned}
\mathrm{T} \sin \theta-\mathrm{mg}=0 \quad & \left(\text { as } a_{y}=0\right) \\
\Rightarrow \sin \theta & =\mathrm{mg} / \mathrm{T}_{\max } \\
& =(.2 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right) /(50 \mathrm{nt}) \\
& =.039 \\
\Rightarrow \quad \theta= & 2.247^{\circ} .
\end{aligned}
\end{aligned}
$$

c.) We now know the angle that corresponds to the velocity at which the string will give up and break. With that information we can use N.S.L. in the center-seeking direction to bring the velocity term into play (that equation was derived above--it is re-derived below for your convenience). Doing so yields:

$$
\begin{aligned}
\frac{\sum \mathrm{F}_{\mathrm{c}}:}{\mathrm{T} \cos \theta} & =\mathrm{m} \mathrm{a} \\
& =\mathrm{m}\left[\mathrm{v}^{2} /(\mathrm{L} \cos \theta)\right] \\
\Rightarrow \mathrm{v} & =\left[\mathrm{LT}(\cos \theta)^{2} / \mathrm{m}\right]^{1 / 2} \\
& =\left[(1.2 \mathrm{~m})(50 \mathrm{nt})\left(\cos 2.247^{\circ}\right)^{2} /(.2 \mathrm{~kg})\right]^{1 / 2} \\
& =17.3 \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

Notice how close this is to the solution determined in Part $a$. The reason for this should be obvious. The string-breaking velocity is high which means the string-breaking angle is small. Being so, the vertical tension component (this must equal $m g$ ) will be small in comparison to the overall tension $T$ and the horizontal tension component will very nearly equal $T$. The assumption we made in Part $a$ was that the tension was all in the center-seeking (horizontal) direction--in this case, that wasn't a bad assumption to make.
d.) For this part, we must incorporate the velocity into our analysis (we didn't do that when we were looking for the angle in Part b; you should understand the difference between these two situations). Using the f.b.d. shown in Part b-i, we can use N.S.L. to write:

$$
\begin{aligned}
& \frac{\sum \mathrm{F}_{\mathrm{c}}:}{} \\
& \mathrm{T} \cos \theta=\mathrm{m} \mathrm{a} \\
&=\mathrm{m}\left[\mathrm{v}^{2} /(\mathrm{L} \cos \theta)\right] \\
& \Rightarrow \mathrm{v}=\left[\mathrm{TL}(\cos \theta)^{2} / \mathrm{m}\right]^{1 / 2}
\end{aligned}
$$

(Equation A).
In this case, we don't know $T$. Looking at the vertical forces yields:

$$
\begin{aligned}
\frac{\sum F_{v}:}{T} \sin \theta-m g & =0 \quad\left(\text { as } a_{y}=0\right) \\
\Rightarrow T & =m g / \sin \theta
\end{aligned}
$$

Substituting $T$ into Equation A:

$$
\begin{aligned}
\mathrm{v} & =\left[\mathrm{T}(\cos \theta)^{2} \mathrm{~L} / \mathrm{m}\right]^{1 / 2} \\
& =\left[(\mathrm{mg} / \sin \theta)(\cos \theta)^{2} \mathrm{~L} / \mathrm{m}\right]^{1 / 2} \\
& =\left[(\mathrm{g} / \sin \theta)(\cos \theta)^{2} \mathrm{~L}\right]^{1 / 2} \\
& =[\mathrm{g}(\cot \theta)(\cos \theta) \mathrm{L}]^{1 / 2}
\end{aligned}
$$

NOTE: If you don't like the use of the cotangent function (cos/sin), forget it and simply use the sine and cosine terms as presented.

Putting in the numbers, we get:

$$
\begin{aligned}
\mathrm{v} & =\left[\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)\left(\cot 30^{\circ}\right)\left(\cos 30^{\circ}\right)(1.2 \mathrm{~m})\right]^{1 / 2} \\
& =4.2 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

### 5.13)

a.) The gravitational force between you and the earth, using Newton's general gravitational expression, is:

$$
\begin{aligned}
\mathrm{F}_{\mathrm{g}} & =\mathrm{G} \mathrm{~m} \mathrm{you}_{\mathrm{e}} \mathrm{~m}_{\mathrm{e}} / \mathrm{r}^{2} \\
& =\left(6.67 \mathrm{x} 10^{-11} \mathrm{~m}^{3} / \mathrm{kg} \cdot \mathrm{~s}^{2}\right)(70 \mathrm{~kg})\left(5.98 \times 10^{24} \mathrm{~kg}\right) /\left(6.37 \times 10^{6} \mathrm{~m}\right)^{2} \\
& =688 \mathrm{nts} .
\end{aligned}
$$

Using $m_{y o u} g$ :

$$
\begin{aligned}
\mathrm{F}_{\mathrm{g}} & =\mathrm{m}_{\mathrm{you}} \mathrm{~g} \\
& =(70 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \\
& =686 \mathrm{nts} .
\end{aligned}
$$

The discrepancy is due to round-off error.
Note: The reason we can get away with using $m g$ when near the earth's surface is due to the fact that the earth's radius is so large. That is, it really doesn't matter whether you are on the earth's surface or 200 meters above the earth's surface. For all intents and purposes, the distance between you and the center of the earth is going to be, to a very good approximation, the same.
b.) Let's begin by determining the amount of normal force $\left(N_{w / o}\right.$ c.f. $)$ the earth must apply to you when you stand at the poles. The f.b.d. for the situation is shown to the right. Noting that there is no centripetal acceleration at the poles (at the poles the rotational speed of the earth is zero), $a_{y}$ is zero and N.S.L. yields:

$$
\begin{aligned}
& \sum \mathrm{F}_{\mathrm{y}}: \\
& \mathrm{N}_{\mathrm{w} / 0 \text { c.f. }}-\mathrm{mg}_{\mathrm{w} / \mathrm{o} \text { c.f. }}=0 \quad\left(\text { as } \mathrm{a}_{\mathrm{y}}=0\right) \\
& \Rightarrow \mathrm{N}_{\mathrm{w} / o ~ c . f .}=\mathrm{mg}_{\mathrm{w} / \mathrm{o} \text { c.f. }} \\
&=(70 \mathrm{~kg})\left(9.83 \mathrm{~m} / \mathrm{s}^{2}\right) \\
&=688.1 \text { newtons. }
\end{aligned}
$$

Note that at the equator, the earth's rotational speed is equal to the distance a point on the equator travels in one day (i.e., the circumference = $\left.2 \pi R=(2)(3.14)\left(6.37 \times 10^{6} \mathrm{~m}\right)=4 \times 10^{7} \mathrm{~m}\right)$ divided by the time it takes to do the traveling (i.e., 24 hours $=86,400$ seconds), or:

$$
\begin{aligned}
\mathrm{v}_{\mathrm{eq}} & =\mathrm{d} / \mathrm{t} \\
& =\left(4 \times 10^{7} \mathrm{~m}\right) /(86,400 \mathrm{sec}) \\
& =463.2 \mathrm{~m} / \mathrm{s} \quad \text { (this is around } 1000 \mathrm{mph}) .
\end{aligned}
$$

Let's now determine the amount of normal force $\left(N_{w}\right.$ c.f. $)$ the earth must apply to you when you stand at the equator. The f.b.d. for the situation is shown to the right. Noting that as there is centripetal acceleration at the equator (at the equator there is rotational speed in the amount calculated above), $a_{y}$ is non-zero and
 N.S.L. yields:

$$
\begin{aligned}
& \underline{\sum F_{c}:} \\
& \mathrm{N}_{\mathrm{w} \text { c.f. }}-\mathrm{mg}_{\mathrm{w} / \mathrm{o} \text { c.f. }}=-\mathrm{ma} \mathrm{c}_{\mathrm{c}} \\
& =-m\left(v^{2} / R\right) \\
& \Rightarrow \quad \mathrm{N}_{\mathrm{w} \text { c.f. }}=\mathrm{mg}_{\mathrm{w} / \mathrm{o} \text { c.f. }}-\mathrm{m}\left(\mathrm{v}^{2} / \mathrm{R}\right) \text {. }
\end{aligned}
$$

Put in a different context, the normal force required at the equator will be equal to the normal force required without centripetal force (remember, $N_{\text {w/o c.f. }}=m g_{\text {w/o c.f. }}$ from above) minus the centripetal force (this will numerically equal $m v^{2} / R$ ) required to move you into circular motion. Putting in the numbers yields:

$$
\begin{aligned}
\mathrm{N}_{\mathrm{w} \text { c.f. }} & =\mathrm{mg}_{\mathrm{w} / o \mathrm{c.f.}}-\mathrm{m}\left(\mathrm{v}^{2} / \mathrm{R}\right) \\
& =(688.1 \mathrm{nts})-(70 \mathrm{~kg})\left[(463.2 \mathrm{~m} / \mathrm{s})^{2} /\left(6.37 \times 10^{6} \mathrm{~m}\right)\right. \\
& =685.7 \mathrm{nts} .
\end{aligned}
$$

If we wanted to define a gravitational constant $g_{e q u}$ that, when multiplied by your mass gives the amount of force the earth must exert on you when you stand at the equator (that is exactly how the $g$ value you have come to know and love was originally determined), $g_{e q u}$ will be:

$$
\begin{aligned}
\mathrm{N}_{\mathrm{w} \text { c.f. }}=\mathrm{mg}_{\mathrm{w} \text { c.f. }} & \\
\Rightarrow \quad \mathrm{g}_{\mathrm{w} \text { c.f }} & =\mathrm{N}_{\mathrm{w} \text { c.f. }} / \mathrm{m} \\
& =(685.7 \mathrm{nts}) /(70 \mathrm{~kg}) \\
& =9.796 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
$$

c.) Defining the distance between the earth and moon to be $r$ and using N.S.L., we get:

$$
\begin{aligned}
& \frac{\sum \mathrm{F}_{\mathrm{c}}:}{-\mathrm{G} \mathrm{~m}_{\mathrm{e}} \mathrm{~m}_{\mathrm{m}} / \mathrm{r}^{2}}=\begin{aligned}
& -\mathrm{m}_{\mathrm{m}} \mathrm{a}_{\mathrm{c}} \\
& =-\mathrm{m}_{\mathrm{m}} \mathrm{v}^{2} / \mathrm{r} \\
\Rightarrow \quad \mathrm{v} & =\left(\mathrm{Gm}_{\mathrm{e}} / \mathrm{r}\right)^{1 / 2} \\
& =\left[\left(6.67 \times 10^{-11} \mathrm{~m}^{3} / \mathrm{kg} \cdot \mathrm{~s}^{2}\right)\left(5.98 \times 10^{24} \mathrm{~kg}\right) /\left(3.84 \times 10^{8} \mathrm{~m}\right)\right]^{1 / 2} \\
& =1019 \mathrm{~m} / \mathrm{s} .
\end{aligned}
\end{aligned}
$$

Interesting Note: Just as two objects will accelerate at the same rate (assuming neither gets close to its terminal velocity) under the influence of gravity, the velocity required to pull a mass in a given-radius circular path does NOT depend upon the mass of the object being so motivated. This might not be immediately obvious (just as the first statement in this NOTE wasn't obvious back when you first ran into it), but it is supported by the math. The moon is the mass being centripetally accelerated, and the $m_{m}$ terms do cancel out in our velocity equation as derived above.
