## CHAPTER 9 -- ROTATIONAL MOTION II

9.1) A sketch for this set-up is shown to the right, complete with f.b.d. for the forces acting on the system. Notice that although the frictional force acts everywhere on the axle, it provides nothing more than a torque on the system. For that reason, we can assume that the net frictional force acts at one place only (it doesn't matter how it's oriented-- $x$ and $y$ components aren't relevant when determining torques). Also, the normal force $N$ at the pin, which does not provide a torque to the system, cannot be vertical as $F$ has $x$ and $y$ components that $N$ must counter.
a.) The request for the magnitude of the angular acceleration should bring to mind
 componts that $N$ must N.S.L. Using the rotational counterpart of that law and assuming the pulley is a disk whose $I_{c m}=(1 / 2) m R^{2}$, we get:

$$
\begin{array}{rc}
\frac{\sum \Gamma_{\text {pin }}:}{} & \\
\Gamma_{\mathrm{f}}+\Gamma_{\mathrm{F}} & =\quad \mathrm{I} \\
\mathrm{f}(.2 \mathrm{R})-\mathrm{FR} & =-\left[(1 / 2) \mathrm{MR}^{2}\right] \alpha
\end{array}
$$

Dividing out an $R$ yields:

$$
\begin{gathered}
(7 \mathrm{nt})(.2)-(12 \mathrm{nt})=-.5(8 \mathrm{~kg})(.6 \mathrm{~m}) \alpha \\
\Rightarrow \quad \alpha=4.42 \mathrm{rad} / \mathrm{sec}^{2}
\end{gathered}
$$

b.) The relationship between the rotating object's angular acceleration $\alpha$ and the instantaneous translational acceleration $a$ of a point (2/3) $R$ from the axis of rotation is $a=r \alpha$. Noting that $r$ is numerically equal to (2/3) $R$, but that $r$ 's units are meters/radian, we get:

$$
\begin{aligned}
\mathrm{a} & =\mathrm{r} \alpha \\
& =(2 \mathrm{R} / 3) \alpha \\
& =.67(.6 \mathrm{~m} / \mathrm{rad})\left(4.42 \mathrm{rad} / \mathrm{s}^{2}\right) \\
& =1.78 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
$$

c.) The rotational counterpart to Newton's Second Law, written in terms of angular momentum, is "the sum of the torques equal to the change of the angular momentum with time," or $\Gamma_{n e t}=\Delta L / \Delta t$. Using this:

$$
\begin{aligned}
& \frac{\sum \Gamma_{\mathrm{pin}}}{}: \\
& \Gamma_{\mathrm{f}}+\Gamma_{\mathrm{F}}
\end{aligned}=\Delta \mathrm{L} / \Delta \mathrm{t} .
$$

As the initial angular momentum is zero (the wheel is initially at rest), multiplying both sides by $t$ gives us:

$$
\begin{aligned}
& {[(7 \mathrm{nt})(.2)(.6 \mathrm{~m})-(12 \mathrm{nt})(.6 \mathrm{~m})] \mathrm{t}=\mathrm{L}_{5}} \\
& \quad \Rightarrow \quad \mathrm{~L}_{5}=[(7 \mathrm{nt})(.12 \mathrm{~m})-(7.2 \mathrm{nt} \cdot \mathrm{~m})][5 \mathrm{sec}] \\
& \quad=-31.8 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}
\end{aligned}
$$

Note: The negative sign means the rotation is clockwise.
d.) Using the rotational form to angular momentum, we know that $L=$ $I \omega$. Using that relationship to determine the angular velocity at $t=5$ seconds, we find:

$$
\begin{aligned}
\mathrm{L}_{5} & =\mathrm{I} \omega_{5} \\
\Rightarrow \quad \omega_{5} & =\mathrm{L}_{5} /\left(.5 \mathrm{MR}^{2}\right) \\
& =\left(-31.8 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}\right) /\left[.5(8 \mathrm{~kg})(.6 \mathrm{~m})^{2}\right] \\
& =-22.08 \mathrm{rad} / \mathrm{sec}
\end{aligned}
$$

e.) Whenever you are asked to determine an angular VELOCITY, think conservation of energy (at least to start). Note that whereas the work done by a force $F$ as a body displaces a distance $d$ is $\boldsymbol{F} \cdot \boldsymbol{d}$ (equal to $F d$ if the force and displacement are in the same direction), the work done by a torque $\Gamma$ applied through an angular displacement $\Delta \theta$ will be $\Gamma \Delta \theta$ (remember, planar rotation is one-dimensional). Friction-produced torques will always do negative work. Torques that make a body's angular velocity increase will do positive work; those that make a body's angular speed decrease will do negative work. Keeping this in mind, the conservation of energy implies:

$$
\begin{gathered}
\sum \mathrm{KE}_{1}+\sum \mathrm{U}_{1}+\sum \mathrm{W}_{\mathrm{ext}}=\sum \mathrm{KE}_{2}+\sum \mathrm{U}_{2} \\
0+0+\left[-\Gamma_{\mathrm{f}} \Delta \theta+\Gamma_{\mathrm{F}} \Delta \theta\right]=(1 / 2) \mathrm{I} \omega_{5}{ }^{2}+0 \\
{[[-(.2 \mathrm{R}) \mathrm{f}] \Delta \theta+\mathrm{FR} \Delta \theta]=.5\left(.5 \mathrm{MR}^{2}\right) \omega_{5}{ }^{2}}
\end{gathered}
$$

$$
\begin{gathered}
{\left[-(.2)(.6 \mathrm{~m})(7 \mathrm{nt})(55.15 \mathrm{rad})+(12 \mathrm{nt})(.6 \mathrm{~m})(55.15 \mathrm{rad})=.25(8 \mathrm{~kg})(.6 \mathrm{~m})^{2} \omega_{5}{ }^{2}\right.} \\
\Rightarrow \quad \omega_{5}^{2}=487.16 \mathrm{rad}^{2} / \mathrm{sec}^{2} \\
\Rightarrow \quad \omega_{5}=22.07 \mathrm{rad} / \mathrm{sec}
\end{gathered}
$$

Note: Remember, the conservation of energy yields magnitudes only.
f.) Using rotational kinematics while knowing that the initial angular velocity is zero and the angular acceleration is $4.4 \mathrm{rad} / \mathrm{sec}^{2}$, we get:

$$
\begin{aligned}
\Delta \theta & =\omega_{1} \mathrm{t}+(1 / 2) \alpha \mathrm{t}^{2} \\
& =0 \quad+.5\left(4.42 \mathrm{rad} / \mathrm{s}^{2}\right)(5 \mathrm{~s})^{2} \\
& =55.25 \mathrm{rad} .
\end{aligned}
$$

g.) Using kinematics:

$$
\begin{aligned}
\omega_{5} & =\omega_{1}+\quad \alpha t \\
& =0+\left(4.42 \mathrm{rad} / \mathrm{s}^{2}\right)(5 \mathrm{~s}) \\
& =22 \mathrm{rad} / \mathrm{sec}
\end{aligned}
$$

( . . . close enough).
9.2) The thing to remember whenever you have a massive pulley is that the tension on either side of the pulley will be different.
a.) This is a Newton's Second Law problem. F.b.d.'s are shown to the right and on the next page, and N.S.L. is presented below (notice that you end up needing FIVE independent equations to solve this problem):
$\underline{\text { for mass } m_{1}}$ :

$$
\begin{aligned}
& \frac{\sum \mathrm{F}_{\mathrm{y}}:}{} \mathrm{N}-\mathrm{m}_{1} \mathrm{~g}=\mathrm{m}_{1} \mathrm{a}_{\mathrm{y}}=0 \quad\left(\text { as } a_{y}=0\right) \\
& \quad \Rightarrow \mathrm{N}=\mathrm{m}_{1} \mathrm{~g} .
\end{aligned}
$$

$$
\underline{\sum F_{x}}:
$$

$$
-\mu_{\mathrm{k}} \mathrm{~N}+\mathrm{T}_{1}=\mathrm{m}_{1} \mathrm{a}
$$

$$
\Rightarrow \quad \mathrm{T}_{1}=\mathrm{m}_{1} \mathrm{a}+\mu_{\mathrm{k}} \mathrm{~m}_{1} \mathrm{~g} .
$$

Note: This presents a problem. We don't want the acceleration $a$ of the mass $m_{1}$, we want the angular acceleration $\alpha$ of the pulley. We need a relationship between those two quantities. Noticing that the string's acceleration $a$ is that of $m_{1}$ and the string's acceleration is also the acceleration of a point on the pulley's circumference, we can use the relationship $a=R \alpha$ for the job. Doing so yields:

$$
\begin{aligned}
& \mathrm{T}_{1}=\mathrm{m}_{1} \mathrm{a}+\mu_{\mathrm{k}} \mathrm{~m}_{1} \mathrm{~g} \\
& \mathrm{~T}_{1}=\mathrm{m}_{1}(\mathrm{R} \alpha)+\mu_{\mathrm{k}} \mathrm{~m}_{1} \mathrm{~g} .
\end{aligned}
$$

for mass $m_{h}$ :

$$
\begin{aligned}
& \underline{\sum F_{y}}: \\
& \quad \mathrm{T}_{2}-\mathrm{m}_{\mathrm{h}} \mathrm{~g}=-\mathrm{m}_{\mathrm{h}} \mathrm{a} \\
& \quad \Rightarrow \mathrm{~T}_{2}=-\mathrm{m}_{\mathrm{h}} \mathrm{a}+\mathrm{m}_{\mathrm{h}} \mathrm{~g} \\
& \quad \Rightarrow \mathrm{~T}_{2}=-\mathrm{m}_{\mathrm{h}}(\mathrm{R} \alpha)+\mathrm{m}_{\mathrm{h}} \mathrm{~g} .
\end{aligned}
$$

for the pulley:

$$
\begin{aligned}
& \frac{\sum \Gamma_{\text {pulley axis }}:}{} \\
& \Gamma_{\mathrm{T}_{1}}-\Gamma_{\mathrm{T}_{2}}=-\mathrm{I}_{\mathrm{p}} \quad \alpha \\
& \mathrm{~T}_{1} \mathrm{R}-\mathrm{T}_{2} \mathrm{R}=-\left[(1 / 2) \mathrm{M}_{\mathrm{p}} \mathrm{R}^{2}\right] \alpha
\end{aligned}
$$

Note that the negative sign in front of the $I_{p} \alpha$ term denotes that the $\alpha$ term is a magnitude and the unembedded sign is designating a clockwise angular acceleration. Dividing out an $R$ yields:

$$
\mathrm{T}_{1}-\mathrm{T}_{2}=-\left[(1 / 2) \mathrm{M}_{\mathrm{p}} \mathrm{R}\right] \alpha
$$

Substituting the expressions for $T_{1}$ and $T_{2}$ we get:

$$
\begin{gathered}
\mathrm{T}_{1} \\
{\left[\mathrm{~m}_{1}(\mathrm{R} \alpha)+\mu_{\mathrm{k}} \mathrm{~m}_{1} \mathrm{~g}\right]} \\
\Rightarrow \quad-\left[-\mathrm{m}_{\mathrm{h}}(\mathrm{R} \alpha)+\mathrm{T}_{2} \mathrm{~g}\right]=-\left[(1 / 2) \mathrm{M}_{\mathrm{p}} \mathrm{R}\right] \alpha \\
\Rightarrow \quad \alpha=\left[-\mu_{\mathrm{k}} \mathrm{~m}_{1} \mathrm{~g}+\mathrm{m}_{\mathrm{h}} \mathrm{~g}\right] /\left[\mathrm{m}_{1} \mathrm{R}+\mathrm{m}_{\mathrm{h}} \mathrm{R}+.5 \mathrm{M}_{\mathrm{p}} \mathrm{R}\right]
\end{gathered}
$$

Put in the numbers and you should come out with $29.32 \mathrm{rad} / \mathrm{sec}^{2}$.
b.) The acceleration of a point on the edge of the pulley (this is also the acceleration of the string which, in turn, is the acceleration of the hanging mass), is $a=r \alpha$, where $r$ in this case is the radius $R$ of the pulley and $\alpha$ is provided from Part $\alpha$ above. Doing the work yields:

$$
\begin{aligned}
\mathrm{a} & =\mathrm{R} \alpha \\
& =(.1875 \mathrm{~m} / \mathrm{rad})\left(29.32 \mathrm{rad} / \mathrm{sec}^{2}\right) \\
& =5.5 \mathrm{~m} / \mathrm{s}^{2} .
\end{aligned}
$$

c.) The total work done by all the tension forces in the system equals zero. Noting that, the conservation of energy yields:

$$
\begin{array}{cc}
\sum \mathrm{KE}_{1}+\sum \mathrm{U}_{1}+\sum \mathrm{W}_{\mathrm{ext}} & =\quad \sum \mathrm{KE}_{2} \\
0+\mathrm{m}_{\mathrm{h}} \mathrm{gh}+(-\mathrm{fh})=\left[(1 / 2) \mathrm{m}_{1} \mathrm{v}^{2}+(1 / 2) \mathrm{m}_{\mathrm{h}} \mathrm{v}^{2}+(1 / 2) \mathrm{I}_{\mathrm{cm}} \omega^{2}\right]+0 .
\end{array}
$$

Noting that the velocity of a point on the pulley's circumference will equal $v$, and that $v=R \omega$, and the frictional force is $\mu_{k} N=\mu_{k} m_{1} g$, we can write:

$$
\mathrm{m}_{\mathrm{h}} \mathrm{gh}=\left[\left(\mu_{\mathrm{k}} \mathrm{~m}_{1} \mathrm{gh}\right)+(1 / 2) \mathrm{m}_{1}(\mathrm{R} \omega)^{2}+(1 / 2) \mathrm{m}_{\mathrm{h}}(\mathrm{R} \omega)^{2}+(1 / 2)\left[\mathrm{I}_{\mathrm{cm}} \omega^{2}\right] .\right.
$$

Rewriting this, eliminating the units (for space):

$$
\begin{gathered}
(1.2)(9.8)(1.5)=(.7)(.4)(9.8)(1.5)+.5(.4)(.1875)^{2} \omega^{2}+.5(1.2)(.1875)^{2} \omega^{2}+.5\left[1.4 \times 10^{-3}\right] \omega^{2} \\
\Rightarrow \quad \omega=21.66 \mathrm{rad} / \mathrm{sec} .
\end{gathered}
$$

d.) Noting that the string will have a velocity equal to that of both $m_{1}$ and $m_{h}$ AND to a point on the circumference of the pulley, we can relate the angular velocity of the pulley and the string's velocity by $v=R \omega$.
Remembering that the units for $R$ in this usage are "meters/radian," we get:

$$
\begin{aligned}
\mathrm{v} & =\mathrm{R} \omega \\
& =(.1875 \mathrm{~m} / \mathrm{rad})(21.66 \mathrm{rad} / \mathrm{sec}) \\
& =4.06 \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

e.) This is a trick question. The acceleration is going to be the same no matter how far the hanging mass has fallen. The answer was derived in Part b.
f.) Angular momentum is defined rotationally as $L=I \omega$. With that we get:

$$
\begin{aligned}
\mathrm{L} & =\mathrm{I} \omega \\
& =\left[(1 / 2) \mathrm{m}_{\mathrm{p}} \mathrm{R}^{2}\right] \omega \\
& =.5(.08 \mathrm{~kg})(.1875 \mathrm{~m})^{2}(21.66 \mathrm{rad} / \mathrm{sec}) \\
& =.03 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s} .
\end{aligned}
$$

9.3) An f.b.d. for the beam is shown below.
a.) This is a rigid body (i.e., equilibrium) problem. The easiest way to get the tension in the line is to sum the torques about the pin (that will eliminate the need to deal with $H$ and $V$ and will additionally give you an equation that has only one unknown--the $T$ variable you are looking for).

## Note:

--Call the distance between the pin and the cable's connection to the beam $d$ $=(2 / 3) L$, where $L$ is the beam's length.
--The angle between $T$ and $d$ is $90^{\circ}$ which means the torque due to $T$ about the pin will be $T d \sin 90^{\circ}=T(2 / 3) L$.
--The distance between the pin and the hanging mass's connection to the beam is $L$.
--The component of $L$ perpendicular to the line of the hanging mass (i.e., $r$ perpendicular) will be $L \cos 30^{\circ}$ (this is like determining the shortest distance between the pin and the line of the force). That means the torque provided by the hanging mass will be $\left(m_{h} g\right) L \cos 30^{\circ}$. As this torque will try to make the beam rotate clockwise, it is a negative torque.
--The beam's mass can be assumed to be located at the beam's center of mass at $L / 2$.

Putting all this together, N.S.L. yields:

$$
\frac{\sum \Gamma_{\mathrm{pin}}:}{\Gamma_{\mathrm{T}} \quad+\quad \Gamma_{\mathrm{m}_{\mathrm{h}}}+\quad \Gamma_{\mathrm{m}_{\mathrm{b}}} \quad=0 \quad(\text { as } \alpha=0)}
$$

$\mathrm{T}[(2 / 3) \mathrm{L}]-\left(\mathrm{m}_{\mathrm{h}} \mathrm{g}\right) \mathrm{L} \cos 30^{\circ}-\left(\mathrm{m}_{\mathrm{b}} \mathrm{g}\right)(\mathrm{L} / 2) \cos 30^{\circ}=0$.

Canceling the $L ' s$ and solving for $T$, we get:

$$
\begin{aligned}
\mathrm{T} & =\left[\left(\mathrm{m}_{\mathrm{h}} \mathrm{~g}\right) \cos 30^{\circ}+\left(\mathrm{m}_{\mathrm{b}} \mathrm{~g}\right)(.5) \cos 30^{\circ}\right] /(2 / 3) \\
& =\left[(3 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.87)+(7 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.5)(.87)\right] /[.67] \\
& =82.7 \mathrm{nts} .
\end{aligned}
$$

Knowing $T$, we can sum the forces in the $x$ and $y$ directions to determine $H$ and $V$. Doing so yields:

$$
\begin{aligned}
& \underline{\sum F_{x}}: \\
& -\mathrm{T} \cos 60^{\circ}+\mathrm{H}=\mathrm{ma} \mathrm{x}_{\mathrm{x}} \\
& =0 \quad \text { as } \mathrm{a}_{\mathrm{x}}=0 . \\
& \Rightarrow \quad \mathrm{H}=\mathrm{T} \cos 60^{\circ} \\
& =(82.7 \mathrm{nt})(.5) \\
& =41.35 \mathrm{nts} \text {. } \\
& \underline{\underline{F} F_{y}:} \\
& T \sin 60^{\circ}+V-m_{h} g-m_{b} g=m a_{y} \\
& =0 \quad\left(\text { as } a_{y}=0\right) \\
& \Rightarrow \mathrm{V}=-\mathrm{T} \sin 60^{\circ}+\mathrm{m}_{\mathrm{h}} \mathrm{~g}+\mathrm{m}_{\mathrm{b}} \mathrm{~g} \\
& =-(82.7 \mathrm{nt})(.87)+(3 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)+(7 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \\
& =26.05 \mathrm{nts} \text {. }
\end{aligned}
$$

Note: If there had been a negative sign in front of the 26.05 newtons, it would have meant that we had assumed the wrong direction for the force $V$. The magnitude would nevertheless have been correct.
b-i.) The moment of inertia about an axis other than one through the center of mass but parallel to an axis of known moment of inertia that is through the center of mass is determined using the Parallel Axis Theorem. The moment of inertia about the beam's pin is:

$$
\begin{aligned}
\mathrm{I}_{\mathrm{p}} & =\mathrm{I}_{\mathrm{cm}}+\mathrm{mh}^{2} \\
& =(1 / 12) \mathrm{m}_{\mathrm{b}} \mathrm{~L}^{2}+\mathrm{m}_{\mathrm{b}}(\mathrm{~L} / 2)^{2} \\
& =(1 / 3) \mathrm{m}_{\mathrm{b}} \mathrm{~L}^{2} \\
& =(1 / 3)(7 \mathrm{~kg})(1.7 \mathrm{~m})^{2} \\
& =6.74 \mathrm{~kg} \cdot \mathrm{~m}^{2}
\end{aligned}
$$

b-ii.) The moment of inertia of a point mass (i.e., the hanging mass) $r$ units from a reference axis (note that $r=L$ in this problem) is:

$$
\begin{aligned}
\mathrm{I}_{\mathrm{hm}} & =\mathrm{mr}^{2} \\
& =\mathrm{m}_{\mathrm{h}} \mathrm{~L}^{2} \\
& =(3 \mathrm{~kg})(1.7 \mathrm{~m})^{2} \\
& =8.67 \mathrm{~kg} \cdot \mathrm{~m}^{2} .
\end{aligned}
$$

b-iii.) The total moment of inertia about the pin is the beam's moment of inertia about the pin added to the hanging mass's moment of inertia about the pin, or:

$$
\begin{aligned}
\mathrm{I}_{\text {tot }, \mathrm{pin}} & =\mathrm{I}_{\mathrm{p}}+\mathrm{I}_{\mathrm{hm}} \\
& =\left(6.74 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)+\left(8.67 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right) \\
& =15.4 \mathrm{~kg} \cdot \mathrm{~m}^{2}
\end{aligned}
$$

c.) Angular acceleration--think N.S.L. Summing up the torques about the pin (the beam is executing a pure rotation about the pin--no reason to sum torques about any other point) and putting that equal to the moment of inertia ABOUT THE PIN times the angular acceleration about the pin yields:

$$
\begin{aligned}
& \underline{\sum \Gamma_{\mathrm{pin}}}: \\
& \Gamma_{\mathrm{T}}+\Gamma_{\mathrm{m}_{\mathrm{hm}}}+\quad \Gamma_{\mathrm{m}_{\mathrm{b}}} \quad=\mathrm{I}_{\text {tot,pin }} \alpha \\
& \mathrm{T}[(2 / 3) \mathrm{L}]-\left(\mathrm{m}_{\mathrm{h}} \mathrm{~g}\right) \mathrm{L} \cos 30^{\circ}-\left(\mathrm{m}_{\mathrm{b}} \mathrm{~g}\right)(\mathrm{L} / 2) \cos 30^{\circ}=\mathrm{I}_{\text {tot }, \text { pin }} \alpha \text {. }
\end{aligned}
$$

The line has been cut (which means $T=0$ ) and we know the total moment of inertia about the pin from above. Using this we get:

$$
\begin{aligned}
& \Gamma_{\mathrm{T}}+\underset{\mathrm{m}_{\mathrm{h}}}{ }+\frac{\Gamma_{\mathrm{m}_{\mathrm{b}}}}{}=\mathrm{I}_{\text {tot,pin }} \alpha \\
& 0
\end{aligned}
$$

Solving for $\alpha$ we get:

$$
\begin{aligned}
\alpha & \left.=\left[\left(\mathrm{m}_{\mathrm{h}} \mathrm{~g}\right) \mathrm{L} \cos 30^{\circ}+\left(\mathrm{m}_{\mathrm{b}} \mathrm{~g}\right)(\mathrm{L} / 2) \cos 30^{\circ}\right)\right] /\left(15.4 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right) \\
& =\left[(3 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(1.7 \mathrm{~m})(.87)+(7 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.85 \mathrm{~m})(.87)\right] /\left(15.4 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right) \\
& =6.11 \mathrm{rad} / \mathrm{sec}^{2}
\end{aligned}
$$

d.) Knowing the angular acceleration of the beam just after it lets loose allows us to determine the translational acceleration of any point on the beam using $a=r \alpha$, where $r$ is the distance between the pin and the point-in-question. In this case, that distance is $L / 2$. Using this information, we get:

$$
\begin{aligned}
\mathrm{a} & =\mathrm{r} \alpha \\
& =[(1.7 \mathrm{~m}) / 2]\left(6.11 \mathrm{rad} / \mathrm{sec}^{2}\right) \\
& =5.19 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
$$

e.) This is a conservation of energy problem. The beam has potential energy wrapped up in the fact that its center of mass will have fallen a vertical distance equal to (L/2) $\sin 30^{\circ}$ during the freefall. That means that its initial potential energy will be $m_{b} g(L / 2) \sin 30^{\circ}$ while its final U will be zero. The hanging mass also falls a vertical distance equal to $L \sin 30^{\circ}$.

The potential energy changes of both bodies (i.e., the beam and hanging mass) must be taken into account if we are going to use conservation of energy--the approach of choice whenever we are looking for a velocity-type variable.

Assuming we approach the beam as though it were executing a pure rotation about its pin, we can relate the change in the potential energy of the system before the snip to the rotational kinetic energy of the beam about the pin plus the translational kinetic energy of the hanging mass just as the beam becomes horizontal. Using that approach:

$$
\begin{array}{rlrl}
\Sigma \mathrm{KE}_{1}+ & \sum \mathrm{U}_{1} & +\sum \mathrm{W}_{\mathrm{ext}} & =\sum \mathrm{KE}_{2} \\
0+\left[\mathrm{m}_{\mathrm{b}} \mathrm{~g}\left((\mathrm{~L} / 2) \sin 30^{\circ}\right)+\mathrm{m}_{\mathrm{h}} \mathrm{~g}\left(\mathrm{~L} \sin 30^{\circ}\right)\right]+0 & =\left[(1 / 2) \mathrm{m}_{\mathrm{h}} \mathrm{v}^{2}+(1 / 2) \mathrm{I}_{\mathrm{p}} \omega^{2}\right]+0
\end{array}
$$ Noting that the velocity of a point on the beam will equal $v=R \omega$, we can write the velocity of the hanging mass as $v_{h}=(L) \omega$ :

$$
\begin{aligned}
& m_{b} g\left((L / 2) \sin 30^{\circ}+m_{h} g\left(L \sin 30^{\circ}\right)=(1 / 2) m_{h} \quad v_{h}^{2}+(1 / 2) \quad I_{p} \quad \omega^{2}\right. \\
& m_{b} g\left((L / 2) \sin 30^{\circ}+m_{h} g\left(L \sin 30^{\circ}\right)=(1 / 2) m_{h}[L \omega]^{2}+(1 / 2)\left[(1 / 3) m_{b} L^{2}\right] \omega^{2} .\right.
\end{aligned}
$$

Putting in the numbers while eliminating the units (for space), we get:

$$
\begin{gathered}
(7)(9.8)(.85)(.5)+(3)(9.8)(1.7)(.5)=.5(3)\left(1.7^{2}\right) \omega^{2}+.5(.33)(7)(1.7)^{2} \omega^{2} \\
\Rightarrow \quad \omega=2.62 \mathrm{rad} / \mathrm{sec} .
\end{gathered}
$$

f.) The translational velocity of the center of mass will be:

$$
\begin{aligned}
\mathrm{v} & =(\mathrm{L} / 2) \omega \\
& =[(1.7 \mathrm{~m}) / 2](2.62 \mathrm{rad} / \mathrm{sec}) \\
& =2.23 \mathrm{~m} / \mathrm{s} .
\end{aligned}
$$

g.) Angular momentum is defined rotationally as $L=I \omega$, where $I$ is the TOTAL moment of inertia for the beam and hanging mass about the pin, and the fact that the length of the beam has been defined as $L$ turns out to be a really, really bad choice of variables (it's the same as angular momentum). Remembering that $I_{t o t, p i n}=15.4 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}$, we get:

$$
\begin{aligned}
\mathrm{L} & =\mathrm{I} \omega \\
& =[15.4](2.62 \mathrm{rad} / \mathrm{sec}) \\
& =40.35 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s} .
\end{aligned}
$$

h.) Angular momentum is conserved if and only if all the torques acting on the system are internal (i.e., are the consequence of the interaction of the various parts of the system). Gravity is an external force which means that any torque it produces on the beam will be an external torque. In short, angular momentum should not be conserved.
(This should be obvious given the fact that the beam is accelerating angularly).
9.4) The merry-go-round's mass is $m_{m}=225 \mathrm{~kg}$ while each child's mass is $m_{c}=35 \mathrm{~kg}$. The radius of the merry-go-round is $R=2.5$ meters and its angular velocity is $\omega_{1}=.8$ radians/second when the kids climb on.
a.) An angular velocity of $\omega_{1}=.8 \mathrm{rad} / \mathrm{sec}$ produces a translational velocity of $r \omega=(2.5 \mathrm{~m})(.8 \mathrm{rad} / \mathrm{sec})=2 \mathrm{~m} / \mathrm{s}$ at the edge of the merry-go-round (i.e., where the children are when they first jump on). Also, the moment of inertia of one child when he or she first jumps onto the merry-go-round is $I_{c, 1}=m_{c} R^{2}=(35 \mathrm{~kg})(2.5 \mathrm{~m})^{2}=218.75 \mathrm{~kg} \cdot \mathrm{~m}^{2}$ while the moment of inertia of the merry-go-round itself is assumed to be that of a disk and is equal to $I_{m}$ $=(1 / 2) m_{m} R^{2}=.5(225 \mathrm{~kg})(2.5 \mathrm{~m})^{2}=703 \mathrm{~kg} \cdot \mathrm{~m}^{2}$. Using conservation of energy, we can write:

$$
\begin{aligned}
\sum \mathrm{KE}_{1}+\sum \mathrm{U}_{1}+\sum \mathrm{W}_{\mathrm{ext}} & =\sum \mathrm{KE}_{2}+\sum \mathrm{U}_{2} \\
0+0+3[(\mathrm{RF}) \Delta \theta] & =\left[3(1 / 2) \mathrm{I}_{\mathrm{c}} \omega_{2}{ }^{2}+(1 / 2) \mathrm{I}_{\mathrm{m}} \omega_{2}{ }^{2}\right]+0
\end{aligned}
$$

Note: $\Gamma_{\text {one kid on } m g r}=R F \sin 90^{\circ}$. The counterpart to $\mathbf{F} \cdot \mathbf{d}$ for rotational motion is $\boldsymbol{\Gamma} \cdot \Delta \boldsymbol{\theta}$, so the three kids do $3[(\mathrm{RF}) \Delta \theta]$ worth of extra work on the m.g.r.

Solving, we get:

$$
\begin{aligned}
3(2.5 \mathrm{~m})(15 \mathrm{nt}) \Delta \theta= & {\left[3(.5)\left(218.75 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)(.8 \mathrm{rad} / \mathrm{s})^{2}+.5\left(703 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)(.8 \mathrm{r} / \mathrm{s})^{2}\right] } \\
& \Rightarrow \quad \Delta \theta=3.87 \mathrm{radians} .
\end{aligned}
$$

Note that the relationship between angular displacement and linear displacement is:

$$
\begin{aligned}
\Delta \mathrm{s} & =\mathrm{R} \Delta \theta \\
& =(3.87 \mathrm{rad})(2.5 \mathrm{~m} / \mathrm{rad}) \\
& =9.68 \text { meters } .
\end{aligned}
$$

b.) Once the kids have climbed aboard, the torques acting on the system are all internal. That is, they are due to the interaction of the system's parts (the kids act on the merry-go-round while the merry-goround acts on the kids). That means we can use the conservation of angular momentum:

$$
\begin{aligned}
& L_{1, \text { tot }}=L_{2, \text { tot }} \\
& \left.\begin{array}{ccccccc}
\mathrm{L}_{\mathrm{m}, 1} & + & \mathrm{L}_{\mathrm{c}, 1} & = & \mathrm{L}_{\mathrm{m}, 2} & + & \mathrm{L}_{\mathrm{c}, 2} \\
\omega_{1}+\left(\begin{array}{lll}
+ & \mathrm{I}_{\mathrm{c}, 1} & \omega_{1}
\end{array}\right)= & \mathrm{I}_{\mathrm{m}} & \omega_{2}+[ & \mathrm{I}_{\mathrm{c}, 2} & \omega_{2}
\end{array}\right] \\
& \left(703 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)(.8 \mathrm{r} / \mathrm{s})+\left(656 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)(.8 \mathrm{r} / \mathrm{s})=\left(703 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)\left(\omega_{2}\right)+\left[3(35 \mathrm{~kg})(1 \mathrm{~m})^{2} \omega_{2}\right] \\
& \Rightarrow \quad \omega_{2}=1.35 \mathrm{rad} / \mathrm{sec} \text { and } \\
& \Rightarrow \quad \mathrm{v}_{2}=\mathrm{r} \omega \\
& =(1 \mathrm{~m} / \mathrm{rad})(1.346 \mathrm{rad} / \mathrm{sec}) \\
& =1.35 \mathrm{~m} / \mathrm{s} \text {. }
\end{aligned}
$$

c.) As there are no external torques, the angular momentum should be conserved.

Also, the forces acting on the system are internal so the total momentum of the system will be conserved as the children move toward the merry-go-round's center. It should be noted, though, that this isn't a very
useful fact as far as problem-solving goes. The addition of the momentum components of the children's motion at the beginning and at any time thereafter will be zero.
d.) The forces being exerted on the system are not conservative (the kids burn chemical energy as they move on the merry-go-round), so energy is not conserved.
e.) We have already deduced that energy should not be conserved. Let's see if we were right by calculating the energy in the system just after the kids jumped onto the
 merry-go-round and the energy once they reached the $r=1$ meter point:

$$
\begin{aligned}
& \mathrm{KE}_{1}=\quad \mathrm{KE}_{\mathrm{c}, 1} \quad+\quad \mathrm{KE}_{\mathrm{m}, 1} \\
& =(1 / 2) \mathrm{m}_{\mathrm{c}, 1} \mathrm{v}_{1}{ }^{2}+(1 / 2) \mathrm{I}_{\mathrm{m}} \omega_{1}{ }^{2} \\
& =.5[3(35 \mathrm{~kg})](2 \mathrm{~m} / \mathrm{s})^{2}+.5\left(703 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)(.8 \mathrm{r} / \mathrm{s})^{2} \\
& =435 \text { joules. } \\
& \mathrm{KE}_{2}=\mathrm{KE}_{\mathrm{c}, 2}+\mathrm{KE}_{\mathrm{m}, 2} \\
& =(1 / 2) \mathrm{m}_{\mathrm{c}, 2} \mathrm{v}_{2}{ }^{2}+(1 / 2) \mathrm{I}_{\mathrm{m}} \omega_{2}{ }^{2} \\
& =.5[3(35 \mathrm{~kg})](1.35 \mathrm{~m} / \mathrm{s})^{2}+.5\left(703 \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)(1.35 \mathrm{r} / \mathrm{s})^{2} \\
& =736.3 \text { joules. }
\end{aligned}
$$

Energy is obviously not conserved.
9.5) Among other reasons, this problem was designed to allow you to see that either the pure rotation or the rotation about the center of mass plus translation of the center of mass approaches will work when dealing with either a Newton's Second Law or conservation of energy problem. An f.b.d. for the problem is shown to the right.
a.) Analyzing the wheel problem from a rotation about the center of mass plus translation of the center of mass approach:

This is a N.S.L. problem. We will begin by summing the torques about the center of mass:

$$
\begin{aligned}
& \underline{\sum \Gamma_{\mathrm{cm}}} \text { : } \\
& \operatorname{Tr}_{\mathrm{a}}=\mathrm{I}_{\mathrm{cm}} \alpha \\
& \text { (Equation A). }
\end{aligned}
$$

We have two unknowns here; we need another equation. Consider the sum of the forces in the vertical:

$$
\begin{aligned}
& \sum \mathrm{F}_{\mathrm{v}}: \\
& \mathrm{T}-\mathrm{mg}=-\mathrm{ma} \\
&=-\mathrm{m}\left(\mathrm{r}_{\mathrm{a}} \alpha\right) \\
& \Rightarrow \quad \mathrm{T}\left.=\mathrm{mg}-\mathrm{mr}_{\mathrm{a}} \alpha \quad \text { (Equation } \mathrm{B}\right)
\end{aligned}
$$

Putting Equations $A$ and $B$ together:

$$
\begin{aligned}
& \operatorname{Tr}_{\mathrm{a}}=\mathrm{I}_{\mathrm{cm}} \alpha \\
& \Rightarrow \quad\left(\mathrm{mg}-\mathrm{mr}_{\mathrm{a}} \alpha\right) \mathrm{r}_{\mathrm{a}}=\mathrm{I}_{\mathrm{cm}} \alpha \\
& \Rightarrow \quad \alpha=\left(\mathrm{mgr}_{\mathrm{a}}\right) /\left(\mathrm{I}_{\mathrm{cm}}+\mathrm{mr}_{\mathrm{a}}{ }^{2}\right) \\
&=\left[(.6 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.015 \mathrm{~m})\right] /\left[\left(1.2 \times 10^{-4} \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)+(.6 \mathrm{~kg})(.015)^{2}\right] \\
&=346 \mathrm{rad} / \mathrm{sec}^{2} .
\end{aligned}
$$

b.) We have to use the Parallel Axis Theorem to determine the moment of inertia about the new axis. Doing so yields:

$$
\begin{aligned}
\mathrm{I}_{\mathrm{a}} & =\mathrm{I}_{\mathrm{cm}}+\mathrm{m} \quad \mathrm{~h}^{2} \\
& =\left(1.2 \times 10^{-4} \mathrm{~kg} \cdot \mathrm{~m}^{2}\right)+(.6 \mathrm{~kg})(.015 \mathrm{~m})^{2} \\
& =2.55 \times 10^{-4} \mathrm{~kg} \cdot \mathrm{~m}^{2}
\end{aligned}
$$

c.) Analyzing the wheel problem from a pure rotation approach:

This is a N.S.L. problem. We will begin by summing the torques about the axis .015 meters from the center of mass (call this Point P).

$$
\begin{aligned}
& \underline{\sum \Gamma_{a}:} \\
& (m g) r_{a}=I_{a} \alpha .
\end{aligned}
$$

We determined $I_{\alpha}$ in Part $b$, so all we have to do is solve for $\alpha$ :

$$
\begin{aligned}
\alpha & =\left(\mathrm{mgr}_{\mathrm{a}}\right) / \mathrm{I}_{\mathrm{a}} \\
& =\left[(.6 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.015 \mathrm{~m})\right] /\left(2.55 \times 10^{-4} \mathrm{~kg} \cdot \mathrm{~m}^{2}\right) \\
& =346 \mathrm{rad} / \mathrm{sec}^{2} .
\end{aligned}
$$

Great jumping Huzzahs! Parts $a$ and $c$ match. Both approaches work.
d.) This is a conservation of energy problem. Major note: Work requires that a force act through a distance. Tension acts at the one point on the disk that isn't moving--it acts at the instantaneously stationary point about which the disk rotates. As such, tension acts through no distance and does no work.
--from the pure rotation approach:

$$
\begin{aligned}
& \begin{array}{cccccc}
\sum \mathrm{KE}_{1}+ & \sum \mathrm{U}_{1} & +\quad \sum \mathrm{W}_{\mathrm{ext}} & = & \sum \mathrm{KE}_{2} & +\sum \mathrm{U}_{2} \\
0 & + & \operatorname{mgd} & + & 0 & =
\end{array} \\
& 0+\operatorname{mgd}+0 \quad=\quad(1 / 2) \mathrm{I}_{\mathrm{a}} \omega^{2}+0 \\
& 0+(.6 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.18 \mathrm{~m})+0 \quad=.5\left(2.55 \times 10^{-4} \mathrm{~kg} \cdot \mathrm{~m}^{2}\right) \omega^{2}+0 \\
& \Rightarrow \quad \omega=91.1 \mathrm{rad} / \mathrm{sec} \text {. }
\end{aligned}
$$

--from the rotation about the center of mass plus translation of the center of

$$
\begin{aligned}
& \begin{array}{lll}
\sum \mathrm{KE}_{1} & +\sum \mathrm{U}_{1} & +\sum \mathrm{W}_{\mathrm{ext}}= \\
0 & +\mathrm{mgd} & +0 \mathrm{KE}_{2}
\end{array} \quad+\sum \mathrm{U}_{2} \\
& 0+(.6 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)(.18 \mathrm{~m})+0=\left[.5\left(1.2 \times 10^{-4} \mathrm{~kg} \cdot \mathrm{~m}^{2}\right) \omega^{2}+.5(.6 \mathrm{~kg})[(.015 \mathrm{~m}) \omega]^{2}\right]+0 \\
& \Rightarrow \quad \omega=91.1 \mathrm{rad} / \mathrm{sec} \text {. }
\end{aligned}
$$

Again, we get the same answer no matter which approach we use.
e.) This is trivial, given the fact that you know the angular velocity calculated in Part d.

$$
\begin{aligned}
\mathrm{v}_{\mathrm{cm}} & =\mathrm{r}_{\mathrm{a}} \omega \\
& =(.015 \mathrm{~m} / \mathrm{rad})(91.1 \mathrm{rad} / \mathrm{sec}) \\
& =1.37 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

## 9.6)

a.) As the force per unit length function is $\xi=k x$, it makes sense that $k$ times $\xi$ must have the units newtons per meter. This will be the case if $k$ has the units $n t / m^{2}$.
b.) This is a N.S.L. problem. The moment of inertia of a rod about one end is (1/3) $m L^{2}$, where $m$ is the rod's mass and $L$ is its length. Since a beam is simply a squared off rod, we will take the moment of inertia of the
beam about its pin to be (1/3) $m L^{2}$. There are two torques acting about the pin. To do the problem we need to determine those torques.
--The magnitude of the torque about the pin due to the beam's weight acting at the beam's center of mass (i.e., at $L / 2$ ) is:

$$
\Gamma_{\mathrm{mg}}=(\mathrm{mg})(\mathrm{L} / 2) \sin 90^{\circ} .
$$

--The magnitude of the torque about the pin due to the differential bits of force acting downward on the beam along its length is more difficult to determine. To do so, follow along while considering the figure below.
--The magnitude of the differential force $d F$ acting over a differential length $d x$ applied a distance $x$ meters from the pin will be:

$$
\begin{aligned}
\mathrm{dF} & =\xi \mathrm{dx} \\
& =(\mathrm{kx}) \mathrm{dx} .
\end{aligned}
$$

--The magnitude of the differential torque $\mathrm{d} \Gamma$ about the pin applied by the differential force $d F$ is:

$$
\begin{aligned}
\mathrm{d} \Gamma & =|\mathbf{r}| \quad|\mathbf{F}| \sin 90^{\circ} \\
& =\mathrm{x}(\mathrm{kx} \mathrm{dx}) \\
& =\mathrm{kx}^{2} \mathrm{dx} .
\end{aligned}
$$

--The net torque about the pin will be the sum of the differential torques (i.e., those applied due to the presence of the force distributed along the beam's length) and the torque due to gravity. Remembering that the moment of inertia
differential force on beam
 about the beam's pin is $I_{p i n}=$ (1/3) $m L^{2}$ :

$$
\begin{aligned}
& \frac{\Sigma \Gamma_{\text {pin }}:}{-(m g)(L / 2)-\int_{x=0}^{L}\left(k x^{2}\right) d x=-I_{\text {pin }} \alpha} \\
& \Rightarrow \alpha=\frac{(\mathrm{mg})(\mathrm{L} / 2)+\mathrm{k}\left(\frac{\mathrm{~L}^{3}}{3}\right)}{\left(\frac{1}{3}\right) \mathrm{mL}^{2}} \\
&=\frac{3 g}{2 \mathrm{~L}}+\frac{\mathrm{kL}}{\mathrm{~m}} .
\end{aligned}
$$

## 9.7)

a.) This is a collision problem. Energy is not conserved through the collision because non-conservative forces act during the collision and because the collision was not close enough to being lossless to be approximated as elastic. Momentum is not conserved because the pin applies an external force to the rod. Angular momentum is conserved as there are no external torques (the external force at the pin applies no torque to the system because the pin force is applied at the axis of rotation).

As the rod is massless, we can treat all of the masses in the system as point masses. We know that there are two ways to calculate angular momentum (i.e., by using the magnitude of $\boldsymbol{r} x(m \boldsymbol{v})$ or by using $I \omega$ ), and we know that the moment of inertia of a point mass is $m r^{2}$ (this means the total moment of inertia of the system is $\left.m_{1}(d / 2)^{2}+2 m_{2}(d / 2)^{2}=\left(m_{1}+2 m_{2}\right)(d / 2)^{2}\right)$. With all of this, we can write:

$$
\begin{array}{ccc}
\sum \mathrm{L}_{\mathrm{o}} & = & \sum \mathrm{L}_{\mathrm{f}} \\
\mathrm{~L}_{\text {wad,o }}+2 \mathrm{~L}_{\text {mass }, \mathrm{o}} & = & \mathrm{I}_{\text {tot }}
\end{array} \omega_{1} .
$$

Plugging in the numbers, we get:

$$
\begin{aligned}
&(.9 \mathrm{~kg})(2.8 \mathrm{~m} / \mathrm{s})(1.2 / 2 \mathrm{~m}) \sin 90^{\circ}=\left[(.9 \mathrm{~kg}+2(2 \mathrm{~kg}))(1.2 / 2 \mathrm{~m})^{2}\right] \omega_{1} \\
& \Rightarrow \quad \omega_{1}=.857 \mathrm{rad} / \mathrm{sec} \\
& \Rightarrow \quad \mathrm{v}_{\text {at ends }}=(\mathrm{d} / 2) \omega_{1} \\
&=(1.2 / 2 \mathrm{~m})(.857 \mathrm{rad} / \mathrm{sec}) \\
&=.514 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

b.) As there is essentially no potential energy change through the collision, the total energy change will be wrapped up in the kinetic energy
difference. The initial kinetic energy is all translational, being associated with the wad. The final kinetic energy can be treated as purely rotational. Doing so yields an energy difference of:

$$
\begin{aligned}
\Delta \mathrm{KE} & =\quad \mathrm{KE}_{\mathrm{after}} \\
& =(1 / 2) \quad \mathrm{I}_{\mathrm{tot}} \mathrm{KE}_{\mathrm{bef}} \\
& =.5\left[\left(\mathrm{~m}_{1}+2 \mathrm{~m}_{2}\right)(\mathrm{d} / 2)^{2}\right] \omega_{1}^{2}-(1 / 2)\left(\mathrm{m}_{1}\right) \mathrm{v}_{\mathrm{o}}^{2} \\
& .5\left(\mathrm{~m}_{1}\right) \mathrm{v}_{\mathrm{o}}^{2}
\end{aligned}
$$

Putting in the numbers we get:

$$
\begin{aligned}
\Delta \mathrm{KE} & =.5\left[(.9 \mathrm{~kg}+2(2 \mathrm{~kg}))(1.2 / 2 \mathrm{~m})^{2}\right](.857 \mathrm{rad} / \mathrm{sec})^{2}-.5(.9 \mathrm{~kg})(2.8 \mathrm{~m} / \mathrm{s})^{2} \\
& =-2.884 \text { joules } \quad(\text { energy is lost }) .
\end{aligned}
$$

c.) The net angular displacement of the system can be determined using conservation of energy for the motion after the collision. In fact, the symmetry of the problem makes the calculation particularly easy as the potential energy picked up by the right mass in its transit is equal to the potential energy lost by the left mass. As such, the only potential energy gain will be associated with the position-change of the wad. That means:

$$
\begin{aligned}
\sum \mathrm{KE}_{1}+\sum \mathrm{U}_{1}+\sum \mathrm{W}_{\mathrm{ext}} & =\sum \mathrm{KE}_{2}+\sum \mathrm{U}_{2} \\
(1 / 2) \mathrm{I}_{\mathrm{tot}} \omega_{1}^{2}+0+0 & =0+\mathrm{m}_{1} \mathrm{gh} .
\end{aligned}
$$

where $h$ is the vertical distance above the wad's initial position. Solving for $h$ yields:

$$
\begin{aligned}
\mathrm{h} & =(1 / 2) \mathrm{I}_{\text {tot }} \omega_{1}{ }^{2} /\left(\mathrm{m}_{1} \mathrm{~g}\right) \\
& =(1 / 2)\left[(.9 \mathrm{~kg}+2(2 \mathrm{~kg}))(1.2 / 2 \mathrm{~m})^{2}\right](.857 \mathrm{rad} / \mathrm{sec})^{2} /\left[(.9 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right]\right. \\
& =.073 \text { meters. }
\end{aligned}
$$

With $h$, we can form a right triangle whose hypotenuse is $d / 2=.6$ meters and whose opposite side is $h=.073$ meters (see the triangle formed in Figure IV on the previous page). Taking the inverse sine yields an angle of .122 radians. That means the rod's net angular displacement

$$
\begin{aligned}
\theta & =\pi+\emptyset \\
& =\pi+\sin ^{-1}[\mathrm{~h} /(\mathrm{d} / 2)]
\end{aligned}
$$

FIGURE IV
will be $\pi$ radians plus .122 radians, or 3.26 radians.

Note: As we know the energy lost from Part b, we could have used the modified conservation of energy equation through the collision. Doing so would have yielded:

$$
\begin{aligned}
& \sum \mathrm{KE}_{\mathrm{o}}+\sum \mathrm{U}_{\mathrm{o}}+\sum \mathrm{W}_{\mathrm{ext}}=\sum \mathrm{KE}_{1}+\sum \mathrm{U}_{1} \\
& (1 / 2) \mathrm{m}_{1} \mathrm{v}_{\mathrm{o}}^{2}+0+(-2.884 \mathrm{j})=0+\mathrm{m}_{1} \mathrm{gh} \\
& \Rightarrow(1 / 2)(.9 \mathrm{~kg})(2.8 \mathrm{~m} / \mathrm{s})^{2}+(-2.884 \mathrm{j})=(.9 \mathrm{~kg})\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right) \mathrm{h} \\
& \Rightarrow \quad \mathrm{~h}=.073 \text { meters. }
\end{aligned}
$$

9.8) This obviously has within it a collision problem. Through the collision, energy is not conserved because the forces involved in the collision are undoubtedly non-conservative and because the problem's author has not deemed it necessary to imbue the collision with the magical label of elastic. Momentum is not conserved due to the fact that an external force is provided by the pin.
Angular momentum is conserved because the external force at the pin produces no torque on the system.

If we can determine the amount of energy there is in the system just after the collision, we can use conservation of energy to determine the rise of the stick's center of mass after the collision and, from that, the final angle of the stick. As the conservation of angular momentum will allow us to determine the angular velocity of the system just after the collision and, with that, the energy in the system just after the collision, we will begin there.
a.) Assume the before-collision velocity of the block (i.e., after free falling to the bottom of the incline) is $v_{1}$ and the after-collision angular velocity of the stick is $\omega_{2}$. Also, assume the block stays stationary just after the collision. With all that, the angular momentum about the pin is:

$$
\begin{aligned}
\mathrm{L}_{\text {before }} & = \\
\mathrm{L}_{\text {block,bef }}+\mathrm{L}_{\text {rod,bef }} & =\mathrm{L}_{\text {rod,aft }}+\mathrm{L}_{\text {block,aft }} \\
\mathrm{mv}_{1} \mathrm{~d} \sin 90^{\circ}+00 & =\mathrm{I}_{\mathrm{p}, \text { rod }} \omega_{2}+0 \\
& =\left[(1 / 3)(5 \mathrm{~m}) \mathrm{d}^{2}\right] \omega_{2} \\
\Rightarrow \quad \omega_{2} & =(3 / 5) \mathrm{v}_{1} / \mathrm{d}
\end{aligned}
$$

The problem here? We don't know what $v_{1}$ is. To determine that quantity, use conservation of energy during the block's slide down the frictionless incline. Doing so yields:

$$
\begin{gathered}
\sum \mathrm{KE}_{\mathrm{o}}+\sum \mathrm{U}_{\mathrm{o}}+\sum \mathrm{W}_{\mathrm{ext}}=\sum \mathrm{KE}_{1}+\sum \mathrm{U}_{1} \\
0+\mathrm{mg}(.4 \mathrm{~d})+0 \quad=(1 / 2) \mathrm{mv}_{1}^{2}+0 \\
\Rightarrow \quad \mathrm{v}_{1}=[2 \mathrm{~g}(.4 \mathrm{~d})]^{1 / 2} \\
=2.8(\mathrm{~d})^{1 / 2}
\end{gathered}
$$

With $v_{1}$, the angular velocity of the stick just after the collision becomes:

$$
\begin{aligned}
\omega_{2} & =(3 / 5) \mathrm{v}_{1} / \mathrm{d} \\
& =(3 / 5)\left[2.8(\mathrm{~d})^{1 / 2} / \mathrm{d}\right] \\
& =1.68 /(\mathrm{d})^{1 / 2} .
\end{aligned}
$$

We are now in a position to use conservation of energy from the time just after the collision to the time when the stick gets to the top of its motion (see Figure V). Defining the position of both the center of mass of the stick and the position of the block just after the collision to be the potential energy equals zero level for each object, we can write:

$$
\begin{aligned}
& \sum \mathrm{KE}_{2}+\quad \sum \mathrm{U}_{2}+\sum \mathrm{W}_{\mathrm{ext}}=\quad \sum \mathrm{KE}_{3}+\quad \sum \mathrm{U}_{3} \\
& {\left[\mathrm{KE}_{2, \mathrm{bl}}+\mathrm{KE}_{2, \mathrm{st}}\right]+\left[\mathrm{U}_{2, \mathrm{bl}}+\mathrm{U}_{2, \mathrm{st}}\right]+\sum \mathrm{W}_{\mathrm{ext}}=\left[\mathrm{KE}_{3, \mathrm{bl}}+\mathrm{KE}_{3, \mathrm{st}}\right]+\left[\mathrm{U}_{3, \mathrm{bl}}+\mathrm{U}_{3, \mathrm{st}}\right]} \\
& {\left[0+(1 / 2) \mathrm{I}_{\mathrm{p}} \omega_{2}{ }^{2}\right]+[0+0 \quad+0=[0+0 \quad+0+[0+(5 \mathrm{~m}) \mathrm{gh}] \text {. }}
\end{aligned}
$$

Solving:

$$
\begin{gathered}
\Rightarrow \quad .5 \quad \mathrm{I}_{\mathrm{p}, \mathrm{st}} \quad \omega_{2}^{2}=(5 \mathrm{~m}) \mathrm{g} \quad \mathrm{~h} \\
.5\left[(1 / 3)(5 \mathrm{~m}) \mathrm{d}^{2}\right]\left[1.68 /(\mathrm{d})^{1 / 2}\right]^{2}=(5 \mathrm{~m}) \mathrm{g}[(\mathrm{~d} / 2)(1-\cos \theta)] \\
\Rightarrow \quad \theta=.44 \text { radians or } 25.3^{\mathrm{o}} .
\end{gathered}
$$

b.) Assume the block adheres to the stick after the collision. Assume also that the before-collision velocity of the block (i.e., after free falling to the bottom of the incline) is $v_{1}$, the block's moment of inertia about the pin is $m d^{2}$, and the after-collision angular velocity of both the block and stick is $\omega_{2}$. With all this, we can write:

FIGURE V

$$
\begin{array}{cc}
\mathrm{L}_{\text {before }} & = \\
\mathrm{L}_{\text {block,bef }}+\mathrm{L}_{\text {rod,bef }} & =\mathrm{L}_{\text {rodter }} \\
\mathrm{mv}_{1} \mathrm{~d} \sin 90^{\circ}+\quad 0 \quad \mathrm{~L}_{\text {block,aft }} \\
\Rightarrow \quad \mathrm{I}_{\text {pin,rod }} \omega_{2}+\mathrm{I}_{\mathrm{p}, \mathrm{bl}} \omega_{2} \\
\Rightarrow \quad \mathrm{mv}_{1} \mathrm{~d}=\left[(1 / 3)(5 \mathrm{~m}) \mathrm{d}^{2}+\mathrm{md}^{2}\right] \omega_{2}
\end{array}
$$

Canceling $d$ 's and $m$ 's and simplifying, we get:

$$
\omega_{2}=.375 \mathrm{v}_{1} / \mathrm{d}
$$

What is $v_{1}$ ? As derived in Part $a$ :

$$
\mathrm{v}_{1}=2.8 \mathrm{~d}^{1 / 2}
$$

With $v_{1}$, the angular velocity of the stick just after the collision becomes:

$$
\begin{aligned}
\omega_{2} & =.375 \quad \mathrm{v}_{1} \quad / \mathrm{d} \\
& =.375\left[2.8(\mathrm{~d})^{1 / 2}\right] / \mathrm{d} \\
& =1.05 / \mathrm{d}^{1 / 2}
\end{aligned}
$$

We are now in a position to use conservation of energy from the time just after the collision to the time when the stick gets to the top of its motion (Figure V still captures the spirit of this calculation). Defining the position of the center of mass of the meter stick and the position of the block just after the collision to be the potential energy equals zero levels for each object, remembering that the moment of inertia of the block is $m d^{2}$, and noting that if the stick's center of mass rises a distance $h$, the block rises a distance $2 h$ (see Figure V), we can write:

$$
\begin{aligned}
& \sum \mathrm{KE}_{2}+\sum \mathrm{U}_{2}+\sum \mathrm{W}_{\mathrm{ext}}\left.=\sum \mathrm{KE}_{3}+\mathrm{KE}_{2, \mathrm{st}}\right]+0+\sum \mathrm{KE}_{3} \\
& {\left[\mathrm{KE}_{2, \mathrm{bl}}+2 \mathrm{KE}_{3, \mathrm{st}}\right]+\left[\mathrm{U}_{3, \mathrm{bl}}+\mathrm{U}_{3, \mathrm{st}}\right] } \\
& {\left[.5\left(\mathrm{md}^{2}\right) \omega_{2}{ }^{2}+.5 \mathrm{I}_{\mathrm{p}} \omega_{2}^{2}\right]+00+0 }=[0 \mathrm{l}+0 \mathrm{mg}(2 \mathrm{~h})+(5 \mathrm{~m}) \mathrm{gh}]
\end{aligned}
$$

Noting that the stick's moment of inertia about the pin is $I_{p}=(1 / 3)(5 m) d^{2}=$ $(5 / 3) m d^{2}$, we can simplify to get:

$$
\begin{gathered}
.5 \mathrm{md}^{2} \omega_{2}{ }^{2}+.5\left[(5 / 3) \mathrm{md}^{2}\right] \omega_{2}{ }^{2}=\operatorname{mg}[2(\mathrm{~d} / 2)(1-\cos \theta)]+(5 \mathrm{~m}) \mathrm{g}[(\mathrm{~d} / 2)(1-\cos \theta)] \\
\Rightarrow \quad\left[.5 \mathrm{md}^{2}+(5 / 6) \mathrm{md}^{2}\right] \omega_{2}{ }^{2}=[2 \mathrm{mg}+(5 \mathrm{~m}) \mathrm{g}][(\mathrm{d} / 2)(1-\cos \theta)] \\
\left.\Rightarrow \quad 1.33 \mathrm{md}^{2} \omega_{2}{ }^{2}=(7 / 2) \operatorname{mgd}(1-\cos \theta)\right]
\end{gathered}
$$

Using $\omega_{2}=1.05 / d^{1 / 2}$, we find:

$$
1.33 \mathrm{md}^{2}\left[1.05 / \mathrm{d}^{1 / 2}\right]^{2}=(7 / 2) \mathrm{mgd}-(7 / 2) \mathrm{mgd} \cos \theta .
$$

Canceling $m$ 's and the $d$ 's, we get:

$$
\begin{aligned}
& 1.33\left[1.05^{2}\right]=(7 / 2) \mathrm{g}-(7 / 2) \mathrm{g} \cos \theta \\
\Rightarrow \quad & \theta=.293 \text { radians or } 16.8^{\circ} .
\end{aligned}
$$

9.9) This is a slippage problem in which nothing is conserved. Approach such problems with N.S.L. Treat the frictional force involved as an average, and define the time it takes $f_{a v g}$ to bring the two bodies into a pure roll as $\Delta t$.

The f.b.d. for the situation is shown in Figure VI to the right.
Summing the torques acting on
 the small mass, we get:

$$
\begin{aligned}
& \frac{\sum \Gamma_{\mathrm{cm}, 1}:}{-f_{\mathrm{avg}} \mathrm{r}}=\mathrm{I}_{1, \mathrm{~m}}\left(\frac{\omega_{3}-\omega_{0}}{\Delta \mathrm{t}}\right) \\
& \quad \Rightarrow \quad-\mathrm{f}_{\mathrm{avg}} \Delta \mathrm{t}=\left(.5 \mathrm{mr}^{2}\right)\left(\frac{\omega_{3}-\omega_{0}}{\mathrm{r}}\right) \\
& \quad \Rightarrow \quad-\mathrm{f}_{\mathrm{avg}} \Delta \mathrm{t}=(.5 \mathrm{mr})\left(\omega_{3}-\omega_{0}\right) \quad \text { (Equ.A). }
\end{aligned}
$$

In doing a similar summation on the large disk, we will have to unembed the required negative sign inherent within the angular velocity term (we didn't have to do that for $m$ because its angular velocities were both positive and the required negative sign was provided by the fact that $\omega_{o}>\omega_{3}$ ). That calculation yields:

$$
\begin{align*}
& \frac{\sum \Gamma_{\mathrm{cm}, 2}:}{-\mathrm{f}_{\mathrm{avg}} \mathrm{R}}=-\mathrm{I}_{1, \mathrm{M}}\left(\frac{\omega_{4}-0}{\Delta \mathrm{t}}\right) \\
& \quad \Rightarrow \quad \mathrm{f}_{\mathrm{avg}} \Delta \mathrm{t}=\left(.5 \mathrm{MR}^{2}\right)\left(\frac{\omega_{4}}{\mathrm{R}}\right) \\
& \quad \Rightarrow \quad \mathrm{f}_{\mathrm{avg}} \Delta \mathrm{t}=(.5 \mathrm{MR}) \omega_{4}
\end{align*}
$$

Adding Equations $A$ and $B$ yields:

$$
0=.5 \mathrm{mr} \omega_{3}-.5 \mathrm{mr} \omega_{\mathrm{o}}+.5 \mathrm{MR} \omega_{4} .
$$

We need a way to relate $\omega_{3}$ to $\omega_{4}$. This can be done by noting that when the disks are finally rolling without slippage, the translational velocity of each disk at the point of contact must be the same (otherwise, there would be slippage). That means:

$$
\begin{aligned}
\mathrm{v}_{3, \mathrm{edge}}=\mathrm{r} \omega_{3} & =\mathrm{V}_{4, \mathrm{edge}}=\mathrm{R} \omega_{4} \\
\Rightarrow \quad \omega_{4} & =(\mathrm{r} / \mathrm{R}) \omega_{3}
\end{aligned}
$$

Using this, we can write:

$$
\begin{aligned}
& 0= .5 \mathrm{mr} \omega_{3}-.5 \mathrm{mr} \omega_{\mathrm{o}}+.5 \mathrm{MR} \omega_{4} \\
& \Rightarrow \quad 0=.5 \mathrm{mr} \omega_{3}-.5 \mathrm{mr} \omega_{\mathrm{o}}+.5 \mathrm{MR}(\mathrm{r} / \mathrm{R}) \omega_{3} \\
& \Rightarrow \quad \omega_{3}=\frac{\mathrm{m}}{(\mathrm{~m}+\mathrm{M})} \mathrm{w}_{\mathrm{o}} .
\end{aligned}
$$
